Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

Old Series, Vol. LX.
New Series, Vol. VI. } No. 26. WEDNESDAY, DECEMBER 23, 1868. { FIVEPENCE.
Sixpence Stamped.

8vo, cloth, pp. 934, price 18s., free by post.

Neligan's Medicines: their Uses and Mode of Administration, including a complete Conspectus of the British Pharmacopœia, an Account of New Remedies, and an Appendix of Formulæ. Seventh Edition, Revised and Enlarged. By Dr. RAWDON MACNAMARA, Professor of Materia Medica to the Royal College of Surgeons in Ireland, &c.

Fannin and Co., Grafton street, Dublin; Edinburgh: Maclachlan and Stewart; London: Longmans and Co., and Simpkin, Marshall, and Co.

Complete in 1 vol., 8vo, pp. 860, price 16s. (Reprinted from the second edition.)

Clinical Lectures on the Practice of Medicine. By ROBERT JAMES GRAVES, M.D., F.R.S. Edited by J. MOORE NELIGAN, M.D.

Fannin and Co., Grafton street, Dublin.
Longmans, Green, and Co., London.

8vo, pp. 449, price 14s., Illustrated with Wood Engravings.

Clinical Memoirs on Diseases of Women. By ALFRED H. M'CLINTOCK, M.D., F.R.C.S. Hon. Fellow of the Obstetrical Society of London, &c.

Fannin and Co., Grafton street, Dublin.
Longmans, Green, and Co., London.

8vo, Illustrated with Lithographic Plates, Coloured and Plain, pp. 651, price 15s.

Contributions to Medicine and Midwifery. By THOMAS EDWARD BEATTY, M.D., T.C.D.

Fannin and Co., Grafton street, Dublin.
Longmans, Green, and Co., London.

Post 8vo, cloth, price 9s.

Neligan's Practical Treatise on Diseases of the SKIN. Second Edition, Revised and Enlarged by T. W. BELCHER, M.D. Dub., F.K. & Q.C.P. Physician to the Dublin Dispensary for Skin Diseases, &c., &c.

Fannin and Co., Grafton street, Dublin.

Fifth Edition, Corrected and Enlarged, fcap. 8vo, cloth, 12s. 6d.

On the Diseases of Women, including those of PREGNANCY AND CHILDBED. By FLEETWOOD CHURCHILL, M.D., President of the King and Queen's College of Physicians.

Fannin and Co., Grafton street, Dublin.
Longmans, Green, and Co., Dondon.

Now ready, fcap. 8vo, cloth, price 3s. 6d.

THE PRACTICE OF MEDICAL ELECTRICITY, showing the most approved Apparatus, their Methods of Use, and Rules for the Treatment of NERVOUS DISEASES, more especially PARALYSIS and NEURALGIA. By G. D. POWELL, M.D., L.R.C.S.I., &c.

Fannin and Co., Grafton street, Dublin.
Longmans, Green, and Co., London.

Now ready,

THE VISITING LIST FOR 1869.

Medical Account Books for 1869.

Medical Bill Heads and Account Forms. Prospectus, with Specimens and Prices, post free on application.

Practitioner's Private Register of Cases, with Index. For 500 Cases, 5s., by post, 5s. 6d.

Register of Obstetric Cases. This form has been prepared by the Council of the Obstetrical Society of London. For 250 Cases, 2s., by post, 2s. 2d.; for 500 Cases, 3s., by post, 3s. 4d.

J. Smith and Co., Medical Stationers, 52 Long Acre, London, W.C.

COLLIS ON CANCER AND TUMOURS.

Price 14s., with numerous Woodcuts and highly finished Chromo-Lithographs.

ON THE DIAGNOSIS AND TREATMENT OF CANCER, and the Tumours Analogous to it. By MAURICE H. COLLIS, M.B., University of Dublin, F.R.C.S.I., Surgeon to the Meath Hospital and County Dublin Infirmary; sometime Examiner on Surgery to the Queen's University in Ireland, and Member of Council, R.C.S.I., &c.

NEW WORK BY DR. E. HEADLAM GREENHOW.

Now ready, cloth, 8vo, price 7s. 6d.,

CHRONIC BRONCHITIS, ESPECIALLY AS CONNECTED WITH GOUT, EMPHYSEMA, and DISEASES of the HEART. By E. HEADLAM GREENHOW, M D., F.R.C.P., Consulting Physician to the Western General Dispensary; Senior Assistant-Physician to the Middlesex Hospital.

London: Longmans, Green, and Co., Paternoster row.

Nearly ready, Second Edition.

ORTHOPRAXY,

(ὀρθὸς, straight, πράσσειν, to make).

This Manual embraces the treatment of every variety of Deformity, Debility and Deficiency of the Human Body.

By HEATHER BIGG, Assoc. Inst. C.E., Mechanician to the Princess of Wales.

London: John Churchill and Sons; and of the Author, 56, Wimpole street, W.

Now ready, Third Edition, revised and enlarged, 8vo, cloth, 6s.

ON the Immediate Treatment of Stricture of the URETHRA. By BARNARD HOLT, F.R.C.S. Senior Surgeon to the Westminster Hospital.

"Mr. Holt's method of treatment of stricture of the urethra by 'immediate dilatation' is so fully recognised and practised by surgeons of the day, that his work, in which the results of his own practice are recorded, can need no recommendation."—*Lancet.*

"This work will both spread Mr. Holt's already well-earned reputation, and—what he will value far more—will help to lessen human suffering and prolong human life."—*Edin. Med. Journ.*

London: John Churchill and Sons, New Burlington street.

WORKS BY

William Adams, F.R.C.S.,

Surgeon to the Royal Orthopædic and Great Northern Hospitals, &c.

Club-foot: its Causes, Pathology, and Treatment. Being the Jacksonian Prize Essay for 1864. With 100 Engravings. 8vo, cloth, 12s.

The Spine, Lateral and other Forms of Curvature: their Pathology and Treatment. With 5 Plates, and 60 Wood Engravings. 8vo, cloth, 10s. 6d.

On the Reparative Process in Human Tendons after SUBCUTANEOUS DIVISION for the CURE of DEFORMITIES. With 8 Plates. 8vo, cloth, 6s.

A Sketch of the Principles and Practice of SubCUTANEOUS SURGERY. 8vo, cloth, 2s. 6d.

London: John Churchill and Sons, New Burlington-street.

BY DR. BARR MEADOWS

Physician to the National Institution for Diseases of the Skin.

New (Fourth) Edition, cloth, price 2s. 6d.

ERUPTIONS, their Real Nature and Rational Treatment; with Remarks on the Abuse of Arsenic, Mercury, and other reputed Specifics.

London: T. Robinson, 227 Gray's Inn road.

Just published, the Eighth Edition, price 12s. 6d.

HOOPER'S PHYSICIAN'S VADE MECUM: a Manual of the Principles and Practice of Physic, with an Outline of General Pathology, Therapeutics, and Hygiene. Eighth Edition, with Wood Engravings. Revised by

WILLIAM AUGUSTUS GUY, M.B. Cantab., F.R.S.,
Fellow of the Royal College of Physicians, and Physician to King's College Hospital; and

JOHN HARLEY, M.D. Lond., F.L.S.,
Fellow of the Royal College of Physicians, Assistant-Physician to the London Fever Hospital.

London: Henry Renshaw; Whittaker & Co.; Simpkin, Marshall, & Co.; Churchill & Sons; Houlston & Wright. Edinburgh: A. & C. Black; Maclachlan & Stewart. Dublin: Fannin & Co.

{ Registered for Transmission Abroad. }

Preparing for the press (waiting only for two of the Hospitals),

SQUIRE'S PHARMACOPŒIAS OF THE LONDON HOSPITALS.

SECOND EDITION.

It will include all the Pharmacopœias just published, of the following Hospitals:—Consumption, Diseases of the Chest, Guy's, King's College, London, London Ophthalmic, London Fever, Middlesex, St. Bartholomew's, St. George's, St. Mary's, University College, Westminster Ophthalmic, as well as the latest editions of Skin and Westminster.

Small 8vo., price 6s. free by post.

CLINICAL OBSERVATIONS.

BY

SIR HENRY MARSH, BART., M.D.,

Physician to Her Majesty the Queen in Ireland.

COLLECTED AND EDITED BY

JAMES STANNUS HUGHES, F.R.C.S.I.,

Professor of Surgery in the Royal College of Surgeons in Ireland.

CONTENTS.

- PLEURITIC EFFUSIONS.
- EMPYEMA; ITS DIAGNOSIS AND PATHOLOGY.
- ON THE TREATMENT OF EMPYEMA.
- THORACENTESIS IN PNEUMOTHORAX.
- EMPYSEMA OF THE LUNGS.
- LARYNGITIS—ACUTE AND CHRONIC APHONIA.
- DISEASES OF THE LARYNX.
- SPASM OF THE GLOTTIS.
- JAUNDICE.
- TREATMENT OF DIABETES MELLITUS.
- REMARKS ON CHLOROSIS AND HÆMORRHAGE.
- OBSERVATIONS ON THE HÆMORRHAGES.

London; John Churchill and Sons; Dublin: Fannin and Co.; Edinburgh: MacLachlan and Stewart.

NOW READY,

BRITISH PHARMACOPŒIA,

Published under the direction of the General Council of Medical Education and Registration of the United Kingdom, pursuant to the Medical Act (1858). rice, as directed by the Lords Commissioners of her Majesty's Treasury,

Post 8vo, cloth boards ... ... 6s.

The work will be sold to Booksellers only, on application, personally or by letter, o the Registrar of the Medical Council, 32, Soho-square, London, W.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM,

32 Soho square, London, W.

NOTICE.—The Copy of the "Medical Register" to be printed and published in 1869, as directed by the 27th Section of the Act, will contain those names only which appear in the General Register as existing on the 1st day of January, 1869.

It is particularly requested that claims for the registration of first or additional Qualifications, and *notices of alterations of Residence*, may be sent to this Office as soon as possible.

All letters respecting Registration, or the Business of the Medical Council, should be addressed to this Office. The Registrar cannot be answerable for remittances on account of Registration which are addressed to his private residence.

October, 1868.

Just out, and greatly enlarged, Third Edition, post 8vo, 10s.,

DR. TILT'S HANDBOOK OF UTERINE THERAPEUTICS and of DISEASES OF WOMEN.

CONTENTS.—Introduction. Chapters: 1. Modes of Examination. 2. Dietetics. 3. Tonics. 4. Sedatives. 5. Antiphlogistics. 6. Caustics. 7. Emmenagogues. 8. Hæmostatics. 9. Specifics. 10. Displacements. 11. Complication of Uterine Affections. 12. Sterility. 13. India in relation to Diseases of the Womb. 14. Prevention Formulary.

John Churchill and Sons, New Burlington street.

Now clear of the Press, price 12s., the Second Edition of the

INTERPRETER OF DIRECTIONS FOR MEDICINES.

By Dr. FREDERICK PRATT, late Army Medical Department, in Ten Languages, conveniently enlarged.

This work is useful for Medical Gentlemen practising in Seaports or going abroad, is recognised by the Hon. Board of Trade, and in its improved form is a fit adjunct to the Medicine Chests of other Nations, or for Chemists and Druggists in Seaport Towns. The instructions here given have reference to actual practice, all superfluous matter being carefully excluded.

London: Charles Griffin and Co., Stationers' hall court.
Cardiff: C. Wakeford, 245 Bute street.

Just published, Second Edition, 8vo, 1s. 6d.,

DR. THOROWGOOD ON CONSUMPTION and its TREATMENT by the HYPOPHOSPHITES.

London: John Churchill and Sons, New Burlington street.
Dublin: Fannin and Co., Grafton street.

By the same Author, price 3s. 6d.,

THE CLIMATIC TREATMENT OF CONSUMPTION AND CHRONIC LUNG DISEASE.

New Edition, much enlarged.

Lewis, 136 Gower street, W.C.

Just published, Second Edition, price 3s. 6d., extra cloth.

OWEN'S CONSPECTUS:

OR, TABULAR SYNOPSIS OF THE BRITISH PHARMACOPŒIA, 1867,

States the Dose, Operation, and Chief Uses of each article in the B.P.

It also gives the Derivation, Dose, Operation, and Chief Uses of Alnuin, Apocynin, Asclepin, Baptisin, Capsicine, Caulophyllin, Cornin, Cypripedin, Euonymin, Eupatorin (Perfo), Eupatorin, (Purpu), Gelsemin, Geranin, Helonin, Hydrastin, Irisin, Jalapine, Leptandrin, Lupulin, Macrotin, Myricin, Pepsine, Phytolaccin, Populin, Prunin, Rhusin, Rumin, Salicin, Sanguinarin, Scutellarin, Senecin, Xanthoxylin. Contains Short Notes on Aconella, Aldehyde, Alkekengiine, Allantoin, Alloxan, Alloxantin, Aloin, Althein, Amygdaline, Amylene, Anthrakokali, Apiol, Arbutine, Asparagine, Beberine, Berberine, Brucine Caffeine, Calumbine, Cannabine, Cantharidine, Catechin, Cetrarine, Codeia, Colchicine, Colocynthin, Columbine, Conine, Cubebin, Delphine, Emetine, Ergotine, Furfurine, Gentianine, Gingerine, Koussine, Lobelin, Mannite, Narceine, Narcotine, Napthaline, Nicotine, Pancreatine, Picrotoxine, Piperine, Quinidine, Quinoidine, Quassine, Solanine, Sparteine, Thein.

WITH A GLOSSARY.

It is Interleaved throughout with Ruled Paper for Notes, &c.

Reprint of First Edition, price 2s. 6d., still on Sale.

London: Longman and Co: Dublin: Fannin and Co.

Lecture.

CLINICAL LECTURE ON INSUFFICIENCY OF THE AORTIC VALVES.

By S. JACCOUD, M.D.,

PHYSICIAN TO THE HOSPITAL OF ST. ANTOINE, PARIS.

TRANSLATED BY JOHN COCKLE, M.D., M.A.

(Continued from page 536, Vol. V.)

The foregoing considerations are applicable to the majority if the organic diseases of the heart, but, in cases of aortic onsufficiency, a special condition both favours and hastens the fatty, or fibro-fatty degeneration of its contractile tissue.

The heart receives the blood destined for its nutrition, from the coronary arteries, but, by an unique exception, they do not receive their maximum repletion at the moment of the ventricular systole. When the blood is propelled into the aorta by the contraction of the ventricle, it passes in a direction directly perpendicular to the orifices of these vessels, consequently, without entering them, and it would be with difficulty only that the nutritive arteries received a small portion of the systolic wave. This condition (a general one) is further aided in a large proportion of subjects by the relative position of the coronary arteries and sigmoid valves. Frequently, indeed, the orifices open so close to the mitral zone of the aorta that when the valves open during systole, they fall back towards the orifices and close them, in which case, it is certain that the nutritive arteries can receive no blood at the moment of the ventricular systole. During the diastole, on the contrary, everything conspires to secure abundant irrigation of the heart. The valves are closed, and the column of blood assumes a retrograde direction; checked by the closed valves, it finds no egress but by the orifices of the coronary arteries largely open to admit it; a portion of blood enters, and the repletion of the arteries is complete. In fine, the injection of blood into the tissue of the heart occurs, principally (I do not say entirely) at the moment of the ventricular diastole, and the pressure of the retrograde column is the most powerful agent in the occurrence.

Such being the mode in which the normal nutrition of the heart is effected, it is easy to see the great disturbance that would accrue from imperfect closure of the aortic valves. A portion of the aortic column of blood regurgitates into the ventricle during the period of diastole, hence, one reason for a direct diminution of the coronary wave; but more than this, the abnormal egress opened to the passage of the blood by the chink of the insufficiency, lowers, considerably, the retrograde pressure of the blood column upon the patent orifices of the coronary arteries, and this pressure affording the *vis a tergo* for the movement of the blood in the coronary arteries, imparts, finally, to aortic insufficiency the two following effects: diminution of the amount of blood supplied to the coronary arteries, and diminution of the pressure causing this blood to circulate; in other words, the heart receives less blood, and that, under less than normal pressure. The nutrition of the heart is thus fundamentally modified and rendered less active. But this is not all. The diminished volume and tension of the blood in the coronary arteries necessarily, induces a retardation of its course in the corresponding veins. This, again, produces in the venous radicles and in the intermediate capillary network, interstitial *stasis*, augmenting, uselessly, the volume of the heart, and restricting that free interchange of elements which constitutes the supreme act of nutrition.

To such source of disorder, another, acting in a similar manner, may be superadded, viz.: the abnormal pressure exercised upon the cardiac capillaries during the period of diastole by the surplus blood which fills, to a *maximum*, the left ventricle.

Thus, shackled, in the initial act which prepares it—admission of the nutrient blood—shackled in the final act which constitutes it—interchange of the *materièl*—the nutrition of the heart is fatally defective, and its tissue degenerates.

While investigating the nature of the muscular tissue generally, Billroth has shown that it tends to degenerate into connective tissue whenever its nutrition is compromised, and certain researches of Traube have confirmed these results in reference to the heart. The change then, is not simply into fat, as Stokes and Paget supposed, but rather one of a fibro-fatty description. The development of this degeneration is frequently hastened by *myocarditis*, contemporaneously existing with the *endocarditis* which caused the valvular disease.

The intra-cardiac papillary muscles naturally participate in these disorders, and end in atrophy, thus directly compromising the action of the mitral valve. My learned friend, Professor Bamberger, of Würzburg, affirms that the papillary muscles are always hypertrophied in cases of aortic insufficiency. Traube, on the contrary, describes them as being in such cases, always elongated, flattened and atrophied. It seems to me, that these contradictory opinions are quite reconcilable, all depending upon the time the examination is made. At the commencement of compensation, the papillary muscles become hypertrophous in common with the left ventricle; subsequently, when the disease has produced the changes I have described, these muscles, also, participate in the change and atrophize. It is, now, that secondary mitral insufficiency results, assuredly one of the most curious points in the history of the affection. So long as the hypertrophy of the ventricle and papillary muscles keeps pace with the dilatation, the respective dimensions of the mitral orfice and its valves remain unchanged, and the closure of the orifice is complete. But, when the hypertrophy halts and yields to the abnormal state of nutrition, when the muscles of the valves, submitted to an abnormal elongation, begin to waste, when, in a word, dilatation acquires the ascendency, the diameter of the mitral orifice aguments in the same proportion, the zone enlarges, and as the valves preserve their original dimensions, there arises a defect of relation between the curtains of the valves and the aperture they ought to close; the closure is now imperfect, and mitral insufficiency results. Whenever, in the case of a patient known to be suffering from aortic insufficiency, without mitral disease, a murmur, during the first period, is heard at the apex of the heart without anteceding acute disease, we may feel assured of the existence of mitral insufficiency originated by exaggerated dilatation of the left ventricle. This accident is of ill-omen, inasmuch as it denotes a disorder of compensation, though not one of immediate peril. Often, on the contrary, during the first phase of this second period, a favourable change in the state of the circulation and, consequently, in the condition of the patient, is observed; indeed, the mitral incompetence opens out a way of escape for the blood which over-distends the ventricle, and acts as an auxiliary by diminishing the sum total of its work. The ventricle empties itself more easily, the auricles dilate in their turn, and this new phase in compensation may retard for a period more or less long, the accidents of confirmed *asystolie*. In consequence of the considerable degree of dilatation of the heart in the case of our patient, I fancy, that the mitral incompetence, which we have detected, is a secondary lesion precisely of this description.

Whenever the compensation of a cardiac affection is compromised the prognosis becomes serious—this is a general fact; but the gravity of the affection is, nevertheless, not always of the same amount, and, in order to form an accurate judgment, the conditions under which the equilibrium is disturbed, must be carefully borne in mind. Permit me to explain myself. If the disturbance can be referred to some positive exciting cause—exertion, for example, unusual fatigue, bronchitis, or other affection capable of inducing momentary disorder of the circulation already compromised—the prognosis is, under such circumstances, less serious, the derangement of compensation is but an accident and not the result of the natural increase of the cardiac disease, and we may fairly hope that, as soon as the superadded cause disappears, matters will revert to their original condition. This confidence is well-grounded when the compensating equilibrium is destroyed for the first time. But, when the disorder results without any appreciable exciting cause, the prognosis acquires an absolute gravity, and, I would add, becomes at once unfavourable. The asystolie is, then, the immediate result of changes occurring in the cardiac structure, and the mechanism is no longer susceptible of repair because the direct agents of compensation are destroyed. Two conclusions are deducible from these facts. In a case of complete or incomplete *asystolie*, the practitioner should most carefully endeavour to discover the possibly exciting causes of the disturbance, and he should, moreover, scrupulously investigate those cases in which disease is compensated, with especial regard to the disastrous consequences of overfatigue of every description, dietetic errors, and particularly those following exposure to cold.

In the case of our female patient, the rupture of compensation has obviously been the united effect of two exciting causes, over-exertion and obstinate bronchitis. We have seen the beneficial results of repose and appropriate treatment in the case. Nevertheless, I do not believe that this patient can be restored to the state of health she enjoyed prior to her admission into the hospital; she is 69 years old, and has always lived under bad hygienic conditions; her disease dates, at least, 15 years; dilatation of the ventricle has induced secondary mitral insufficiency; the aorta is dilated and atheromatous, and from the existence of these conditions, I am persuaded that the nutrition of the cardiac tissue has been compromised for a long period, and, that the occurrence of *asystolie*, has been but slightly hastened by those extrinsic influences we have alluded to. I do not believe that compensation can be completely re-established. She has been in the hospital four weeks, and during three weeks, at least, the alarming symptoms she first suffered from, have ceased: so long as she remains at rest in bed, all seems well, but, the moment she rises, dyspnœa supervenes, the face acquires a cyanotic tint, and the legs begin to swell; the heart can only perform its proper function while she remains in the horizontal position, consequently, I regard her condition as hopeless. She would, assuredly, very speedily sink, if she were compelled to keep the erect position during the day. Repose may, for a time, prolong existence; this is the only possible hope in her case.

I cannot quit this subject, without pointing out to you the frequency of sudden death in cases of aortic insufficiency. No disease of the heart is exempt from this sudden termination, but it is never more to be dreaded than in cases of this description, and I would particularly recommend to your perusal the work that my friend, and colleague, Dr. Mauriac, has devoted to this point of pathology. Bear well in mind this fact, every patient suffering from aortic insufficiency may die suddenly, whenever the compensation is not perfectly exact. The mechanism of this accident is easily apprehended. Remember that the left ventricle is both dilated and enfeebled; under the influence of exertion, emotion, or any other cause influencing the innervation of the heart, either in a direct or reflex manner, the action of the ventricle is suddenly arrested, and it ceases to contract; the double column of blood from the auricle and the aorta enters and distends its cavity; the degenerated muscular walls have no reactive power, the pause of a second—becomes a definite paralysis, and the faintness,—a mortal syncope.

The cases of Williams, Elliotson, Hope, and many others, demonstrate the fact and the explanation I have offered of it. Occasionally, even, the cessation of the heart's action occurs without any obvious exciting cause. The ventricle, for an instant, forgets its functions as it were, and taken by surprise by the blood which over distends it, loses all power of action, ceases to contract, and the patient dies.

The statistics of Aran enables us to appreciate approximately, the comparative frequency of this termination in aortic insufficiency. This acute observer found that in 113 instances of sudden death from disease of the heart, 25 cases occurred in isolated disease of the aortic valves, and in 9 other cases, simultaneous disease of these valves existed. Thus, 34 deaths out of 113, were to be imputed to disease of the aortic orifice.

This special danger inherent in cases of aortic insufficiency, is of great practical importance. It imposes upon the practitioner a paramont obligation. Under such circumstances he should forewarn the relatives of the patient of the possible danger which threatens life. No other resource remains to lessen beforehand our share of responsibility.

Three months subsequently our patient died, and the autopsy, made by my friend Dr. Pierreson, who discharged temporarily, the duties of *chef de clinique*, confirmed the diagnosis in every particular. The heart was hypertrophied and presented considerable dilatation of the left ventricle; the aortic insufficiency was complete; the aorta itself, sensibly dilated at its ascending portion, was studded by atheromatous deposit, and the curtains of the mitral valve, tough, rigid, and uneven, could no longer close the enlarged orifice.

Postcript.—The translator would remark that many points of detail alluded to had already been pointed out by him in his memoir on "*Insufficiency of the Aortic Valves, in connection with Sudden Death, with Notes, Historical and Critical,*" published by Davies (Hardwicke), 1861. For some years prior to the thesis of Mauriac, he had been investigating the mechanism of the cardiac circulation in health and disease, and had advocated the view of the repletion of the coronary arteries during the period of ventricular diastole. This view was adopted by the late Dr. Snow, in his work on "Chloroform," published in 1858, and, indeed, is now generally adopted.

He had, moreover, shown that there are, practically, *three* well marked stages of aortic insufficiency. First, the *irritative* stage—here, in many cases, the earliest symptoms are those of obstruction and general cardiac excitement, from the impediment offered to the onward passage of the blood, by the tumid state of the aortic valves, and it is only after a certain interval, when this tumid state subsides, that the process of contraction of the valves begins; they then permit regurgitation of the blood into the cavity of the ventricle, causing it to dilate. The speedy accession of hypertrophy of the chamber compensates the disorder thus induced, and forms the second, or *physiological* stage, which, in many cases, if rightly managed, may persist for years, and maintain the proper balance of the circulation. Sooner or later, according to circumstances, the third, or *degenerative* stage occurs, and in its train, the symptoms so well described by Jaccoud, as those of asystole. This stage, the translator has shown, may, in some cases, often be foreshadowed by the gradual lessening of the collapse of the superficial arteries—a fact occasionally noticed even by non-professional observers of the cases.

In concluding this Lecture the Translator feels specially called upon to acknowledge the great and ready courtesy of Professor Jaccoud and Monsieur De la Haye, in permitting its publication. The work from which it is extracted—"*Lecons de Clinique Medicale,*" Paris, 1867—cannot be too strongly commended to the attention of our countrymen as equally calculated by its rare excellence to sustain the high character of the School of Medicine of Paris, and to enhance the reputation of one of its most brilliant teachers.

Original Communications.

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION: THEIR DIAGNOSIS AND TREATMENT.

By S. SCOTT ALISON, M.D. Edin.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

No. I.

The importance of a knowledge of the relations of the disorders of the trachea and adjacent parts, including the larynx, the tonsils, and the pharynx, to pulmonary consumption, has been long admitted by practical physicians.

Before I joined the Consumption Hospital at Brompton, I was sensible of the importance of these relations, but it was after this that its real magnitude was duly impressed upon my mind. Disorders of the trachea and the adjacent parts above indicated have been observed in a very large proportion of the entire cases coming under my care in the hospital. Amongst the forty-three patients—not merely the consumptive—now under my charge in the hospital, no less than twenty-eight present disorders of the parts indicated, thus giving the result of 65 per cent.

The chief relations which have been held to subsist between these throat disorders and pulmonary consumption, are four in number—1. That of a precursor; 2. That of a coincident; 3. That of a sequela; and 4. That of a simulator. These relations are all worthy of note, but in this paper most attention will be given to the fourth relation—viz., that of a simulator.

Precursor.—As a precursor, the disorders above-named perform a comparatively unimportant part. In many cases of phthisis declaring itself soon after the advent of the disorders referred to, I am satisfied the priority was more apparent than real, and that tubercle in the lung was really present before the disorders of the trachea were manifested, and that diligent search for the physical signs of tubercle instituted at the first departure from health would have resulted in the discovery of physical evidence of tubercular disease of the lung. I have met with numerous examples of pulmonary consumption in the history of which, it has been declared by the patient that, the first disordered condition was that of the throat and voice, and that the chest was only secondarily affected. These cases have come before me in large numbers, but I have generally found that the amount of disease in the lungs at my first examination has been so great, as to suggest its comparatively long duration, and the probability of its having been really the primary disorder. In fact, the evidence in a large proportion of cases of phthisis in which throat affections have been held as precursors, the pulmonary disease was the real and primary one, and the supposed precursor was truly a secondary one.

In one sense throat affections may be regarded as precursors—viz., as antecedents, for, of course, persons suffering, or who have suffered, from these complaints are, like all others, more or less liable to become affected with phthisis. Many persons who have suffered from throat complaints become the subjects of pulmonary consumption, but these disorders are more truly antecedents merely—that is, independent prior disorders, performing no part in the production of tubercle in the lung. Primary tubercle of the trachea, if it ever occur at all, we have reason to believe, is an exceedingly rare affection, and the ordinary inflammatory disorders of the trachea and the congested and hypertrophied conditions of the mucous membrane are very different in their nature from tubercle, and seldom or never give rise to it either in the parts primarily disordered or in the lungs. Such is my experience, and such is that of most enlightened practical physicians and pathologists of the present day. True it is, in non-professional parlance, we often hear of neglected colds of the throat spreading down into the lung and producing consumption, and in some not highly esteemed professional writings we read of the same relation. It was Dr. Hunter, of inhalation notoriety, who most recently pressed upon the public this error and false induction.

A Coincident.—Affections of the trachea and adjacent parts do occasionally manifest themselves by hoarseness and other throat indications at the same time that pulmonary consumption gives signs of its development, and the two classes of disorder seem to arise at the same time.

We see this alliance or double development to hold almost exclusively in cases of acute pulmonary consumption. But even in cases of acute consumption signs of tracheal complication seldom develop themselves until the pulmonary and more grave form of disease, together with constitutional disturbance, has held in a marked manner for days or weeks. Therefore as a coincident (beginning at the same time) of pulmonary consumption, tracheal disorder is of comparatively little import.

Sequela.—It is as a sequela of pulmonary consumption that tracheal disorders assume their most grave aspect. Including all forms of pulmonary consumption, and all its stages, we may safely say that few cases are met with which do not present some material evidence of tracheal disturbance.

In the first stage of phthisis the non-implication of the trachea and adjacent parts is most common, but even in such cases a majority will show a not entirely healthy condition of the parts in question. In the second stage a much larger proportion of cases is found to be implicated with these minor affections; and in the third, nearly every case reveals, either by the voice or by respiratory auscultatory signs, evidence of the implication of the windpipe. The task of connecting the disorder of the trachea with the more grave disease of the lung in such cases is, on the whole, an easy one. If there be any difficulty it is in cases of phthisis in its first stage. The aberrations from the healthy amount and quality of the respiration sounds of the chest, serve at once, in the later stages of pulmonary consumption, to indicate the dependence of the minor disorders upon pulmonary mischief.

Of twenty-six cases of all forms of phthisis in all stages of the disease now in the Hospital at Brompton, under my care, nineteen, or 73 per cent., give full evidence of disorder of the upper air-tube apparatus.

Some of the local complications are grave, while others are of less serious significance.

Of eighteen cases of phthisis in the third stage, only three are free from implication of the trachea, and other parts of the upper air-tube apparatus. These figures give a percentage of 83.

The diseases of the trachea, larynx, and adjoining parts, which we observe in pulmonary consumption, are almost invariably found to hold this relation, viz.—that of sequela. In examples of acute pulmonary consumption, it is consistent with my observation to say, that the disorders of the windpipe, &c., that occur, depend upon the extension to the parts first involved, of that tubercular vascular over-action which originated in the lungs. This morbid action is propagated by continuity of structures.

In chronic cases of phthisis, the disorders of the trachea, larynx, and adjoining parts, seem to proceed from the production of congestive action from neighbouring irritative disease, and in the second and third stages from inflammatory conditions, sometimes simple and sometimes tubercular, caused by the actual passage of irritant secretions, and the *debris* of destroyed material from the diseased lung, over hitherto healthy parts.

The morbid alterations of structure which I have observed in the trachea and the adjacent parts, in pulmonary consumption, are various. These conditions are often simply an injected and turgid, and somewhat swollen state of the mucous membrane of the rima of the glottis, the epiglottis, the tonsils, and the posterior wall of the pharynx, and of the larynx and trachea. These parts may be all equally affected, but it is more frequently the case that only some parts are materially involved. In the more advanced cases of phthisis the larynx and trachea are chiefly diseased, but in many examples, rapidly progressing to a fatal issue, all parts are implicated. Red and injected conditions, with small elevations of swollen glandules of the posterior wall of the pharynx are common. Indented or serrated conditions of the epiglottis are often presented, and a thin and shaven-off like edging is not unfrequent. A red and scarlet state of the epiglottis, resembling the petal of a scarlet geranium, is often met with. The larynx is often inflamed, congested, ulcerated, and totally, or almost totally, deprived of its vocal cords. A very general condition, in extremely bad cases, is one of total loss of the cords, with deep ulceration between the thyroid and cricoid cartilages, and a general ulceration, and rough or granulated surface of the entire mucous membrane of the larynx.

The symptoms during life attending the allied disease of the trachea, &c., are, in slight cases, huskiness and occasional hoarseness, sense of irritation in the throat, and more or less frequent attempts to clear the parts of mucus, producing a sound like the word "hem," more or less forcibly formed. The hoarseness frequently becomes continuous, and when ulceration of the larynx is extensive, aphonia or whispering is produced. When the vocal cords are totally destroyed, the aphonia is complete, and the attempt to speak simply produces a roaring and inarticulate sound, very painful to hear. In these latter cases deglutition is painful, and when the epiglottis is greatly ulcerated, particles of food are wont to fall into the larynx and to give rise to partial suffocation, and to severe local convulsive efforts.

An œdematous state of the rima glottidis is occasionally found in the last stages of pulmonary consumption, and this gives rise to great difficulty of respiration. The lung is not duly inflated, and it is impeded in the expulsion of its æriform contents. The voice is destroyed, or becomes whispering, and the sound of respiration, heard through the medium of the open atmosphere, or through the stethoscope placed upon the neck, is hissing and constricted. The greater intensity of the hissing or constriction at the immediate region of the glottis, points to the seat of the constrictive disease.

Tubercular matter, grouped in masses even so small as mustard-seeds, I have never seen in the larynx and trachea, and this product seems, when deposited, to affect very fine forms, scarcely visible to the naked eye, such as I have observed in the aorta and pulmonary artery. The distinct masses of tubercle which we find imbedded in the mucous membrane of the bowels, both small and large, I have never seen imitated in the mucous membrane of the tubular apparatus leading to the lungs. The addition of important throat affections to pulmonary consumption adds seldom to the danger of the patient, but exposes him to grave inconvenience. Difficulty of swallowing tends to hasten dissolution.

The discovery of even advanced disease of the lung is in some cases impeded by the presence of strongly marked signs of disorder of the trachea, &c. The coarse and loud constrictive respiration sound through the upper portion of the air-tube apparatus, tends by descending into the lung structure to mask fine and single humid crackles in cavernules and in cavities. The cavernous voices is with some difficulty made out in cases marked by partial aphonia, and weak and whispered voice. The articulated voice, superficial and very near so valuable as a sign of cavity is, of course, lost in cases of aphonia. I have seen several cavity cases in which, even after very diligent exploration, I have been left in doubt until a second examination has been made. The proportion of such cases is small, for careful listening will generally detect some amount of crackling, either cavernulous or cavernous, and the voice over the diseased lung will generally show an unusual amount of distinctness and nearness. Besides in advanced softening and in cavity cases, the motion is reduced, and the percussion is either dull or of manifestly short duration. Coughing will sometimes give the requisite evidence. In cases of tubercular, perforation of the pleura, the amphoric respiration and voice, and the clear percussion at first throughout the diseased side, and in the stage of effusion the clear percussion above, and the absolutely dull percussion below will almost always suffice to lend certainty to the judgment.

It is right, however, to mention that cases of cavity do sometimes present themselves in which the cavity has been altogether overlooked when such oversight is scarcely to be justified, and this has happened from the marked character of the throat complication causing the chest to be exempted from all exploration. Since very much attention has been given to the laryngoscope, and so much time expended upon its use, these over-lookings seem to have become more than usually frequent. Perhaps this is in some measure to be explained by the fact that the laryngoscope has been largely adopted, and most usefully too, by some members of the profession, who had not previously seen much disease of the chest, or been familiar with the methods of exploration of that portion of the body. Such oversights are not only an injustice to the patient, but discredit the medical attendant, and are likely to prove injurious to him. To avoid all chance of such results it should be made a rule that, in cases of throat disease of any importance, either through the urgency or intractability of local symptoms, or suffering of the general health, the entire chest should be subjected to the tests of expansion, percussion, and auscultation, I would almost say of *differential* auscultation. With this chest examination such errors will not often occur, and should disease subsequently manifest itself, it will be felt that non-discovery did not rest upon culpable neglect.

◆

ON THE ACTION OF ACONITE AND QUININE IN NEURALGIA.

By H. M. JONES, M.D., M.Ch., L.R.C.S.E., L.A.H.Dub.,
PHYSICIAN CORK CITY DISPENSARY, DEMONSTRATOR OF ANATOMY AT THE QUEEN'S COLLEGE, CORK.

(A paper read before the Cork Medical Association.)

Gentlemen,—It is not with a view to enunciate any new theory regarding the action of a drug often experimented with before by such men as Pereira, Gesner, Fleming, and others, that I bring these few remarks under your notice, nor to propound any new doctrine on its therapeutic effects, but being struck often, while conversing with medical men on the action of aconite, by their dislike to administer it internally at all, I was tempted to bring the following case under your notice to-night.

Now, it has not been the ardour of the young physician, nor the love of new and extraordinary means of aid that has occasionally led me to use it, but that like others, struck as a student with the startling effects of aconite, I subsequently became practically convinced of its therapeutic value, and have not been afraid to administer it internally when cases presented themselves which demanded its use. I now wish to allude to its action in neuralgic affections only, and shall illustrate any remarks I make by rather a curious case which I attended this year. In cases where as yet I have had to use aconite, such as in the varying shades of facial neuralgia, cephalagia, &c., I have invariably combined it with quinine, and with astonishing good effect, that is to say, cases that quinine was administered in without any result, on combining aconite with it, I afforded relief.

Thus, having often seen the good results from the combination of these two powerful drugs, I determined to use them as a first means on this particular instance, and then thought that it might be a good example to add to the list of those brought before the profession of the use of aconite.

Mrs. H., aged 72, apparently very strong and robust, I saw on January 16th, 1867, about six P.M., suffering the most excruciating torture, quite unable to speak coherently and shrieking dreadfully from pain. Her daughter explained to me that this had come on violently since three P.M. of the same day, but that for a few days previously, she had suffered slight neuralgic attacks in the arm and side. The old lady writhing in agony directed my attention to her thumb, and from her daughter I learned the following history:—Twenty-five years previously she had injured her hand; the bones of the thumb got affected, and Sir P. Crampton wished to take away a piece of one. This she would not consent to, and five years subsequently, during a period of extreme cold and frost, she got a bad attack of neuralgia, and went to her physician, requesting him to amputate the thumb, so bad was the pain in it.

Though shaken greatly in her general health, she had no return of neuralgia for a period of twenty years, until the severe frost of January of this year again brought it on. I was on the point of examining the thumb, but the moment I touched it, she screamed most violently, and got into such a state, that it completely prevented any further examination, and I refrained, satisfied that she suffered from pure nervine pain propagated by the old lesion in the thumb, and fostered by the extreme cold—she having gone out each day to chapel notwithstanding her daughter's entreaties. My visit was hurried, as I saw that her suffering was so intense, and all she could now say was that if I knew of no other means to alleviate the pain, to get the thumb amputated forthwith.

I ordered immediately—Tinct. aconiti, ʒi. Quinine bisulph. ʒss. Acid sulph. dil, ʒi. Aq. ad. ℥viiim. ℥ss. stat. et rept. omni secr. hora, directing that if anything unusual occurred to send for me at once, but that I'd see her early the next morning. I did so, and to my astonishment, for I thought the amount of relief I might have afforded the old lady, never would have satisfied her. She expressed herself very thankful to me, and I saw at a glance that she was much better. Questioning her regarding any sensation she might feel, she complained of numbness and tingling in her fingers and toes; she had had a few hours sleep in the night after four or five doses of the mixture, and it was after the sleep she awoke so much relieved. She apologised for being, as she said, so like a mad woman on the previous evening. I now ordered the mixture to be given only every third hour, and seeing her the same evening so much better, I discontinued the use of the aconite, and reduced the dose of the quinine. She then recovered completely, and I have not since seen her. I tried the strength of the tincture. I used it in this instance, as follows:—I selected a fine buck-rabbit, and having kept it some hours previously without food, gave it ten drops of the tinct.—

1st. Ten drops—no effect.

2nd. Ten drops, one hour after: spasms about the throat and twitchings about its mouth set in.

3rd. Ten drops, one hour after last: more spasms, limited to the mouth and throat.

4th. Ten drops, one hour after last: more spasms, limited to the mouth and throat.

5th. Twenty drops, half-an-hour after: great difficulty of breathing, and spasms of jaws.

6th. Half-an-hour after, twenty drops: same result, increased in energy.

7th. Twenty drops, half an hour after: violent convulsions of all the body, jerkings of head and hind limbs, the latter thrown alternately out, and gaspings; death in about half a minute after the dose, so that *less* than ʒii of this tincture produced death, divided over a period of more than four hours. We may notice, in this case I have quoted a few points:—1st. The effects of severe cold in developing a disorder latent for so many years, as also that the thumb had recovered the effects of the injury, *it* was the part to originate the general disorder of the nerves of the arm, shoulder, and face. 2nd. The rapid subsidence of such severe pain under the combined influence of aconite and quinine.

Now, before answering the question as far as pathology and physiology will allow us: How do aconite and quinine combined, or aconite alone, effect an neuralgic patient? We must first decide what is neuralgia? and here is the first difficulty; without entering into varied discussions we may take as the results of the researches of those interested in this curious affection, that it is due to some morbid change in the nerves of parts often not *recognisable* after death, as slight thickening, vascularity, or pressure from tumours in their immediate neighbourhood, these changes being the active causes which are set in motion by external or internal agencies, as atmosphere in the first case, or stomach and intestinal disorders in the second, both alike giving rise to intense suffering traceable often to no cause, but this external or internal agency which produces, in some unknown manner, a state of increased sensibility of the nerves of sensation of certain regions not even evidenced by any visible changes in these parts, or again to some low state of vitality of certain peripheral nerves, consequent on a disordered condition of surrounding structures, or the direct result of any *injury*.

Looking, now, practically as to the manner in which aconite given internally can be a remedy for any of those morbid states:—1st. As a contro-stimulant, either by a direct action conveyed to parts by the blood, as evidenced by the numbness and diminished sensibility, this influence being felt by parts preternaturally excited before acting on the system generally (Fleming). 2nd. By a direct sedative action on the circulation as shown by its action on the heart's pulse. 3rd. By diminished power of sensibility of the brain—it being, as Bouchardat states, a stupifying agent, less powerful than belladonna or opium. We may thus make a two-fold division of its mode of action on a neuralgic part.

1st. Reducing any increased vascularity and excitability.

2nd. Exercising a healing influence on the nerves of the part, and deadening sensibility in the nerves of the affected region, both effects being increased in proportion as it influences the nervous system generally through the brain; and, as Dr. Fleming remarks, "if an organic lesion, resulting from an injury, be not present, our cure may be permanent," if it is only temporary, the physician, always remembering the physiological action of aconite, must seek for those states of the system which contro-indicate its use, and not stigmatise a drug as noxious and dangerous, which, if given in congested states of organs, lungs, or otherwise, will decidedly verify his worst anticipations; or if in anæmic states of the system we give this powerful drug, we must only blame our own rashness, if its indiscriminate use leads us into trouble.

To enter into the vexed question of the exact way in which quinine acts, whether it is a tonic, acting simply by catalysis (Headland) on the blood, or by giving to it some essential ingredient in which it is deficient. For my part, I must confess myself an advocate of the logical conclusions drawn by Dr. Headland on this matter in his recent able edition on the "Action of Medicines," believing quinine to be a restorative medicine, not directly neurotic, and adducing in evidence the discovery of Dupré and Jones by means of the fluorescent test, which establishes the presence of a substance in the blood similarly constituted to quinine. Certain it is that quinine is not excreted in any quantity, and it requires very large doses to detect its presence in the urine. To satisfy myself of this fact, I obtained some pure *quinia* from the Apothecaries' Hall, Dublin, and gave, at intervals, to a healthy man (a pensioner) 33 grains in the 24 hours. He suffered from pains in the loins, head, and back. I got him to pass urine immediately before the first dose, and obtained, then, all he passed in the 24 hours, amounting to 54 fluid ounces. It was quite clear and *healthy*. I first took two ounces and rendered it slightly acid with tartaric acid, evaporated to dryness, dissolved in absolute alcohol, and evaporated in a water-bath, filtered, and extracted the residue, and repeated this process three times. I then extracted the residue with more alcohol, to which remainder, by this time very minute and colourless, I added solution of carbonate of potash, and got a *white precipitate*, perfectly soluble in æther, but failed to get the chlorine and ammonia test on the evaporation of the ether. On again repeating the same process with four ounces of this urine, I got the green with chlorine and ammonia, but from the quantity I obtained altogether from the six ounces, I should say that not more than a few grains passed entirely through the urine. We may thus look on quinine as producing a *permanent* change in the blood, either filling up some deficiency, or producing some change in its integral constituents, and so altering the existing state, and conclude that quinine acts through the blood, and that its effects in nervine disorders are due to this blood-action, which is restorative in character. So that it is indicated in any deranged state of the system which clinical experience shows to be the result of certain morbid states of the blood, originating in a deficiency or change in its ingredients, as evidenced by a certain class of affections that follow those particular changes.

Is not, then, neuralgia often the result of such changed conditions of the blood? Pathology, in many instances, can assign no cause for it! Morbid anatomy looks in vain for any state to account for the life symptoms, and though we may have palpable causes during life, and apparent after death, still, in many instances, we can assign no reason for suffering but some debilitated state of the blood, anæmic or otherwise, no practical physician having failed to observe the relation that exists between neuralgia, debility, and hysteria; often do we find all three co-existing in the same individual, and as surely as chlorosis and hysteria are allied, so is neuralgia and other debilitated states. The question arises, then, does not quinine, by altering this morbid state, relieve the condition that it has induced? and this I believe to be its true action. And so we may use it as a valuable adjunct to aconite—1st. In neuralgia occurring in anæmic or debilitated patients, without any apparent nerve-lesion or exciting cause. 2nd. In old cases of neuralgia, where the primary disease has induced a state of the circulation at the part affected not in accordance with health. 3rd. In all cases where, to a temporary relief, we would add permanency of cure.

I trust the society will pardon the time I have taken up on this apparently trivial subject; but I offer my excuse in the words of Dr. Headland, when he says that "it must be confessed that in the action of medicines and their agency in curing disease, we do not so much excel our ancestors;" and he rightly attributes it to the want of united medical testimony on the action of drugs, "so that the doubts and difficulties which are now clearing away before the efforts of a few, may be finally dissipated by the energies of all."

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

REMARKABLE AND VERY RARE CASE OF SPREADING GANGRENE OF THE LEFT UPPER EXTREMITY, RESULTING FROM DISLOCATION OF THE HEAD OF THE HUMERUS INTO THE AXILLA—FATAL TERMINATION—POST-MORTEM APPEARANCES.

UNDER THE CARE OF MR. CROLY.

J. S., aged 73 years, a bricklayer, a powerfully muscular man, and unusually active for his time of life, residing a few miles from the city, was admitted into the Hospital under Mr. Croly's care, on the evening of the 29th of May, on the recommendation of a medical gentleman:—

History.—He was working at a gentleman's house on the 26th of May, and accidentally fell from a ladder; he struck his left arm in the fall, and immediately lost all power of the limb, which swelled rapidly; he felt a coldness and tingling in his fingers. He was visited in two hours by a practitioner of long experience, who at once recognized a luxation of the left shoulder-joint, and was forcibly impressed by the unusual amount of swelling, not only of the hand and forearm, but of the entire upper extremity. The patient was placed on the floor, the surgeon (having taken off his boot) put his heel into the axilla, and grasped the wrist; with the utmost facility the head of the bone was returned into its natural position, and the arm was bandaged to the side.

May 27th.—On visiting the patient he observed that the swelling had not diminished since the reduction, and on examining the shoulder-joint he felt a depression beneath the acromion process, as if the head of the bone had again left the glenoid cavity.

29th.—The patient complained of coldness and total loss of sensation in the fingers. He was then removed to hospital.

Condition of Patient and appearance of limb on admission.—Countenance cheerful and natural; pulse (at *right* wrist) 80 in the minute; tongue clean; left hand cold and very much swollen; nails blue; no sensation in the fingers; forearm swollen and congested, upper arm at least twice the size of the sound limb; no pulse can be felt at the wrist or in the brachial artery. The shoulder-joint (when the elbow is kept in to the side) presents a naturally rounded appearance, but on abducting the arm a depression is observed (beneath the acromion), into which the fingers sink upon pressure.

There is a large soft tumour filling the entire axillary cavity, not diminished in size by compressing the axillary artery in its first stage, and an enormous ecchymosis extending from the superior costa of the scapula to the gluteal region posteriorly, and laterally from within two inches of the dorsal vertebræ to the nipple of the breast.

Treatment.—Hand and forearm enveloped in wadding cotton and supported on a pillow. A liberal supply of nourishment was ordered, and opium with quinine prescribed.

May 30th.—Patient slept well; does not complain of pain; tongue clean; pulse strong and natural in sound arm. There is great tension and infiltration of all the affected limb. There are dark-coloured bullæ on the back of the hand, which presents a bluish appearance.

Mr. Croly consulted with his colleague on duty (Professor Hargrave), who agreed with him as to the propriety of making superficial incisions into the forearm and arm, to relieve tension. This was accordingly done; serous fluid escaped, and the angles of each wound were plugged with strips of lint steeped in turpentine, to prevent hæmorrhage. Immediately after the incisions were made the axillary tumour disappeared.

One of the incisions was made over the course of the brachial artery, and the fascia was opened; but neither Professor Hargrave nor Mr. Croly could feel any pulsation in the vessel.

31st.—Patient in the same cheerful spirits, and apparently not suffering from any constitutional disturbance. Hand of a bluish-black colour; the discoloration has extended as far as the dorsal aspect of the forearm above the wrist. The integuments above the gangrene present a purplish-red appearance on the dorsal aspect, and a mottled look on the anterior part of the forearm, extending obliquely upwards and inwards nearly as high as the elbow-joint.

June 1st.—Patient passed a good night, and has taken eggs beaten up with whiskey, a chop, strong beef-tea, and a liberal supply of wine each day since admission. His countenance is natural, and he is, as usual, very cheerful and hopeful. Pulse full and strong. He passes urine freely, which is not discoloured. A number of flaccid bullæ containing gas and dark fluid have formed on the forearm, and there is a gangrenous odour from the limb.

Mr. Croly drew a line with ink around the forearm, for the purpose of observing the extension of the gangrene.

2nd.—Patient was restless during sleep last night, yet his countenance is not indicative of any distress. Pulse 88, and full. He was ordered a turpentine enema, with tincture of assafœtida, as the bowels were not freed for two days. No tympanites. Continues to enjoy his food, and passes water freely. The gangrene has not extended above the ink-line on the dorsal aspect of the limb, but there are dark streaks above the line marked on the anterior surface. Much of the extravasated blood in the scapular region has been absorbed. Phlyctenæ on limb larger.

Temperature of hand and forearm, 75°
„ upper arm, 95°

3rd.—Patient passed a tolerably good night. Countenance not so bright or cheerful; face sallow; pulse not so strong, and more frequent. The gangrene has spread about three inches above the ink-line. He could not pass water this morning. Mr. Croly introduced the catheter, and drew off healthy-looking urine.

A consultation was held at twelve o'clock noon, and it was decided that amputation at the shoulder-joint should be performed at half-past three o'clock, which proposal the patient and his friends agreed to.

At half-past three o'clock Mr. Croly visited the patient (who was most anxious that something should be done to give him a chance of his life), but found a marked change for the worse in the short time which elapsed since the consultation at noon. The countenance became anxious, respiration accelerated, with dyspnœa; the pulse was rapid, and the patient seemed partly unconscious.

Mr. Croly at once abandoned the idea of operation. The patient expired at eight o'clock P.M.

AUTOPSY SIXTEEN HOURS AFTER DEATH.

Mr. Croly (assisted by his colleagues Professor Hargrave, Mr. Tufnell, and Dr. Hewitt, and in the presence of the class), made a careful dissection of the shoulder-joint and axillary region in the following manner:—

An incision was made, commencing at the centre of the clavicle, and carried in a curved direction to the insertion of the deltoid muscle, and from that point upwards and backwards to the spine of the scapula. On dissecting up the integuments a large quantity of dark-coloured blood was observed infiltrating the subcutaneous tissue. The deltoid muscle, which was largely developed, was reflected upwards so as to expose the joint; large black clots of blood were seen beneath the muscle; the dissection was carefully continued so as to expose the axillary artery and vein. On abducting the arm, an enormous quantity of dark clotted blood was observed, filling the axillary cavity between the subscapular muscle and the ribs. The clots were removed in handfuls, and when the parts were sponged, the axillary artery, at the termination of the third stage of its course, was opened, and a gum-elastic catheter passed through the vessel up to the clavicle, to ascertain if it was wounded. A catheter was also passed through the vein with the same object. The axillary artery and vein were thus carefully examined throughout their three stages, and no lesion of either vessel could be discovered, nor was there any atheromatous deposit in the artery. The subscapular vein (a very large trunk) was found lacerated at its junction with the axillary vein, thus accounting for the hæmorrhage and gangrene. There was not any lesion of the brachial plexus.

On examining the shoulder-joint, the capsular ligament was found divided at its inferior part so fully, that on abducting the arm the head of the humerus could be luxated into the axilla with the greatest facility, the portion of the head of the bone corresponding to the laceration of the capsular ligament, and subscapular vein, presented a well-marked appearance of chronic rheumatic arthritis. A chisel-shaped osseous stalactite of about an inch in length, was developed on the bone at the internal part of the anatomical neck. The upper arm was infiltrated with serum and blood. There was not any rupture of the muscles discovered, and no trace of the long tendon of the biceps could be found in the joint.

Remarks.—The post-mortem examination in this interesting case explained the remarkable facility with which the dislocation was reduced, the joint having exhibited the morbid appearances characteristic of chronic rheumatic arthritis. The chisel-shaped osseous stalactite (an adventitious growth found on the anatomical neck of the humerus) caused the extensive laceration of the capsular ligament.

This peculiar condition of the joint, and the destruction of the articular portion of the long tendon of the biceps usual in this affection, allowed of unnatural mobility of the head of the bone.

The subject has been recently brought under the notice of the profession in an able article by Dr. Adams in the pages of this Journal.

The sudden and enormous swelling and tension of the entire upper extremity, and the subsequent extensive ecchymosis of the scapular region and the side, were found to be the result of laceration of the subscapular vein (a vessel of considerable size), evidently produced by the sharp ridge on the neck of the bone. The gangrene which soon followed was caused by the venous extravasation, which intercepted the circulation through the limb (venous hæmorrhage being probably a more frequent cause of gangrene than arterial lesion). Being an example of spreading gangrene, in which not any appearance of a line of demarcation was observable, the question of amputation was discussed (a procedure recommended in such cases by Larrey, Guthrie, and the lat

Professor Porter, the highest surgical authorities), and although an unpromising case for operation (in consequence of the advanced age of the patient and the extensive ecchymosis of the trunk), it was decided, upon consultation, to afford the sufferer a chance of preserving his life, by amputation at the shoulder-joint (and thus reach the source of the lesion which caused the gangrene), as no constitutional symptoms to contra-indicate the operation had appeared.

The consultation was held at twelve o'clock noon, the operation decided upon, and the hour fixed for half-past three P.M.; but during that brief interval very unfavourable symptoms set in. The operation was accordingly abandoned, and the reasons were fully explained by Mr. Croly to the class which had assembled in the operation theatre.

As far as can be ascertained, the foregoing is not only a very rare, but probably an unique case, and will doubtless be read with interest by the practical surgeon.

The post-mortem examination is very interesting—firstly, in fully explaining the cause of the lesion which produced the fatal gangrene; and secondly, in showing how unsuccessful amputation would have proved, and consequently how hopeless in some cases are the resources of our art.

RICHMOND SURGICAL HOSPITAL.

CASES UNDER THE CARE OF MR. WILLIAM STOKES.

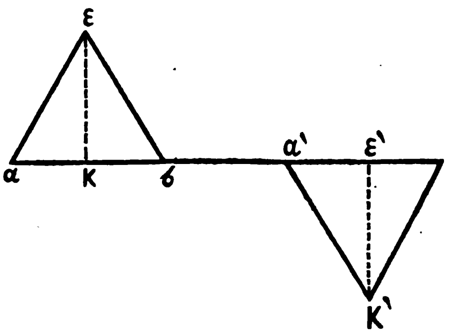
(Reported by Mr. JAMES ROSS.)

EPITHELIOMA OF FOURTEEN YEARS' DURATION SITUATED ON LEFT CHEEK OVER THE MALAR EMINENCE: RECENT RAPID INCREASE OF THE WARTY GROWTH: EXCISION OF THE TUMOUR, AND SUBSEQUENT PERFORMANCE OF BUROW'S PLASTIC OPERATION: SUCCESSFUL RESULT.

As this case is one in which the plastic operation of M. Burow, a Polish surgeon of considerable eminence, was performed, a brief record of the case to its successful termination cannot be considered devoid of surgical importance:—

Phinter D., æt. 60, was admitted into Mr. Stokes' wards in the Richmond Hospital on the 20th of last May. The patient stated that about fourteen years ago he received the prick of a needle in the cheek, in the situation of the tumour, for the removal of which he had come into hospital. Shortly after getting this apparently trivial injury he perceived a small wart about the size of a grain of rice to form exactly in the situation where he got the prick of the needle. This wart remained stationary for a very considerable length of time, after which it seemed to get loosened, and the patient then picked it off with one of his nails. Another then formed in the same situation, and ran precisely the same course. Things remained in this way for several years, the disease being apparently quite localized, and the general health of the patient remaining in every respect perfectly unimpaired. About six months previous to the patient's admission into the Richmond Hospital the warty growth began to increase in size, and when he came under Mr. Stokes' care the tumour was fully half-an-inch in length, and a quarter of an inch in breadth. There was no evidence of any similar disease elsewhere.

After some clinical remarks to the class on the nature of this peculiar form of malignant disease, Mr. Stokes observed that when it occurred in the situation in which it was in the case under observation—viz., on the face, it was of the last importance to the patient that no permanent disfiguring cicatrix should be left in the situation when the tumour was removed. Mr. Stokes proposed to obviate the chance of this occurring by performing a plastic operation after removing the tumour, which would have the much to be desired effect of not leaving any marked cicatricial deformity. The operation alluded to, was one designed originally by a Polish surgeon named Burow, of considerable continental celebrity, the particulars of which Mr. Stokes had learned from seeing the operation performed by M. Arlt, the eminent Professor of Ophthalmology in the Vienna University. The different steps of this ingenious operation were then carefully explained to the class. The patient having been brought full under the influence of chloroform the tumour was encircled by three incisions in the form of a triangle (*a e b*), the apex of the triangle (*e*) being above the tumour, and the base (*a b*) below. The tumour and the portion of the integument to which it was attached were then carefully excised. The incision (*a b*) was then carried outwards until its entire length (*a b'*) was three times that of the base of the triangle (*a e b*). The different steps of this operation will probably be best understood by reference to the annexed woodcut:—



Burow's Plastic Operation.

The next step consisted in making the outer third of this horizontal incision (*a' b'*) the base of a second triangle (*a'* K' *b'*) in every respect equal to the original one (*a e b*), where the tumour was removed. The integument within the incisions, constituting the second triangle (*a' b'* K'), was then carefully dissected off. There were then two raw triangular spaces to be covered in by sound integument, one which had been the seat of the epithelial cancer, and the other in which the integument was perfectly healthy. This was easily effected by dissecting off with great care the triangular flaps (*a a'* K') and (*e b b'*) from the adjacent structures. This having been done, no difficulty whatever was experienced in bringing the points (*a b*) together by one interrupted suture, and the points (*a' b'*) together by another. In this way the triangular spaces were completely filled up, without any chance of a broad cicatrix, which would necessarily have been left had either of them been left to fill up by granulations.

The sutures were left undisturbed for three days, after which they were removed; the greater portion of the wound had united by first intention—indeed, all, except the points corresponding to the apices of the two triangles. In order to promote union at these points, Mr. Stokes inserted two of the finest of the so-called "entomologist" pins, and by a figure of eight suture brought the ununited edges of the wound into close apposition. After two days the pins were removed, when it was found that all the wound had united perfectly. Nothing could have been more entirely satisfactory than the result of this admirably conceived and extremely ingenious plastic operation. This case, as far as Mr. Stokes is aware, is the first in which this operation has been performed in this country, and the particulars of it to its successful termination cannot but prove interesting to those who take an interest in this all-important and thoroughly practical department of operative surgery.

SEVERAL of the old students of St. Thomas's Hospital met at Mr. Whitfield's on the 18th, to consider how, on the rebuilding of the hospital, they might, by some special gift, best testify their attachment to their old school. Drs. Barker, Carpenter, Clapton, Saunders, Messrs. South, Solly, Le Gros Clark, Whitfield, and Stone, with Dr. Sedgwick, 2 Gloucester-terrace, as honorary treasurer and secretary (who will be glad to hear from old students), were appointed a sub-committee to report on the matter to a general meeting to be shortly convened.

Address

DELIVERED AT THE OPENING OF THE GENERAL MEDICAL COUNCIL.

SESSION 1868.

By Dr. BURROWS, F.R.S., President.

GENTLEMEN,—Ten eventful years have transpired since the Legislature created this Council for the performance of most important duties towards the medical profession and the public. For nine of those years I have had the honour of being associated with you in your labours, and for nearly five years by your favour I have occupied the distinguished post of President. The vessel on which we have embarked, when first constructed, excited the scrutiny and criticism of many. When first launched she had to steer her course through unknown or untraversed seas, often through tempestuous waters, with quicksands around us and breakers ahead. She visited ports where her presence was hardly welcome. The original crew, unaccustomed to work together, laboured under serious disadvantages; the crew has sustained many great losses. Some of our foremost men have been taken from us; but still nearly one half survive to recount the dangers of the past, and to assist by their experience those more recently enlisted into an arduous and responsible service. Our craft is still sound, and our crew more disciplined. We have learnt to esteem or appreciate our companions, and let us hope that the venture of the present year may, by our earnest denial of self, by our prudence and circumspection, and close application to our work, bring profit to those whose interests are consigned to our keeping as well as credit to ourselves.

In former years, I have in my opening address ventured to retrace succinctly the proceedings of the previous session, and to indicate some of the questions which you would be called upon to investigate and discuss during the current session; but in consequence of the additional duties assigned to our enlarged Executive Committee, it would be presumptuous on my part to arrogate to myself a duty which must necessarily be more ably performed through the joint labour and wisdom of the members of that Committee.

It is, however, incumbent on me, as your President, to render to you some account how I have performed certain public duties which have devolved upon me personally, as such knowledge may to a certain extent influence you in the course you may think proper to take in the future conduct of the business of the Council. By a resolution of the General Council on June 6, 1867, and also by one passed by the Executive Committee on November 12, 1867, recorded in the Minutes of the Medical Council, vol. v., p. 273, your President became charged with the duty of conferring with the Government respecting the Bill for the Amendment of the Medical Acts.

THE MEDICAL ACTS AMENDMENT ACT.

During the past winter I had various communications with the Government, and more particularly a lengthened interview with the Home Secretary on February 7 last, and on that occasion I again pressed upon Mr. Gathorne Hardy the necessity of Amendments in the Medical Act of 1858, and requested him to give his assistance to the General Medical Council in bringing a Bill into the House of Commons. After a patient hearing of my statement, Mr. Gathorne Hardy frankly said that in the early part of the impending session of Parliament he had so many Government Bills on his hands, that he could hold out no promise of assisting the Medical Council before Easter; but that if the state of public business would permit, at a later period of the session, he would give his attention to the subject. Mr. Hardy at the same time requested me to prepare a short memorandum for him, embracing in a succinct form the points most urgently requiring his attention. With the able assistance of the Registrar (Dr. F. Hawkins), I was preparing this document immediately before the Easter recess, when, as you know, a thunderbolt was thrown on the floor of the House of Commons which startled and amazed the uninitiated, disconcerted all the Government plans, and practically put an end to all legislation for the session. And then commenced what is facetiously termed "the slaughter of the innocents." Bill after Bill was sacrificed, and it was hopeless and useless to press upon the Home Secretary the promise he had held out of assisting the Medical Council to bring in a Bill this session. All prospect of medical legislation having vanished, it seemed unnecessary to summon you from your respective public and private duties until this more than customary advanced period of the year. The Medical Council will therefore be relieved from any pressing necessity of discussing this question, which has often occupied so much of our time.

Although the question of the amendment of the Medical Acts will not be necessarily before you, still, as this in all probability will be the only opportunity I shall have of addressing you from the presidential chair, I would wish to make a few suggestions for the consideration of those who may be called upon hereafter to carry on the negotiations with the government upon the amendment of the Medical Acts.

First, let me recall to the remembrance of the members of this Council that one of the great obstacles to the introduction of a bill into the House of Commons to amend the Medical Act, 1858, was the discordance of opinion between the late Secretary of State for the Home Department (Mr. Walpole) and this Council upon the terms of a clause enabling this Council to admit colonial and foreign graduates on to the British Register. Part of this question is likely to be brought before the Council again this year, in consequence of an application from the University of Melbourne, addressed to the Imperial Government, to have their medical graduates admitted to registration in Great Britain; and also because this Council have already committed themselves by a resolution (June 3rd, 1867), moved by Sir D. Corrigan, and seconded by Mr. Cæsar Hawkins. See Minutes of Council, vol. v., p. 187.

Considering the difficulty that has been experienced in drawing up a clause to effect the registration of colonial and foreign graduates, I would suggest whether the difficulty may not be surmounted without attempting to frame a new clause, but simply by a verbal amendment of the Clause 46 of the Medical Act—the clause which enabled this Council to make special provision for the registration of persons practising medicine and surgery within the United Kingdom on colonial or foreign diplomas and degrees before the passing of the Act.

The operation of Clause 46 was simply retrospective; and the amendment of it that I would suggest would be to make its operation prospective as well as retrospective. Under the powers granted to the Medical Council by that clause, no less than 204 colonial and foreign graduates were admitted on to the British Medical Register, and there is no reason for the Legislature to suspect that this Council would act with less liberality for the future than it has done in the past; and this Council may feel assured that any committee appointed to investigate the claims of colonial and foreign graduates to registration would devote the same patient and careful consideration to the subject as the former committee did, and which was so ably presided over by the distinguished representative of the College of Physicians of Edinburgh, Dr. Alexander Wood. I commend the foregoing suggestion to the impartial consideration of members of Council as a means of evading the difficulty attendant upon drawing up a new clause which shall be equally acceptable to the Government and to this Council.

A second suggestion I would venture to offer for future occasions is that any future application to the Government to assist the Council in Parliament should be made in a different quarter to that hitherto selected. The Home Secretary has always been requested to introduce into the House of Commons our Bill to amend the Medical Acts. The uniform reply that we have received from that Minister has been that the pressure of public business has prevented him from acceding to our wishes, and it ever will be so unless powerful Parliamentary and external pressure is exerted to influence the Home Secretary. It was suggested by Sir George Grey when in office that this measure should be first introduced into the House of Lords. Now, after much experience and reflection on this subject, I am inclined to think that the suggestion that our Bill should be introduced into the House of Lords is not only the course which is most likely to be attended with success, but that it is the course which ought rightly to have been adopted from the first. My reasons for thinking so are as follows. According to the enactments of the Medical Act, 1868, this Council has not properly any relations with the Secretary of State for the Home Department, although the Act happened to be introduced and carried through parliament by a former Home Secretary (Mr. Walpole). On the other hand, this Council partly emanates from and may have most important relations with the Privy Council. In the constitution of the Privy Council you must bear in mind that six of our number—a fourth of the whole—are nominated by her Majesty with the advice of her Privy Council.

Also by clauses 20 and 21 of the Acts we are directed under certain circumstances to make representations to her Majesty's

Most Honourable Privy Council, and not to the Home Secretary. The Privy Council is called upon, if it shall think fit to enforce any representations or regulations emanating from this Council.

Again, by clause 23, it is the Privy Council which is directed to prohibit attempts on our part to impose restrictions upon the practice of medicine and surgery, and the Vice-President of the Committee of the Privy Council on Education is especially directed to take part in any orders connected with carrying out the regulations of this Medical Council.

It appears then from all that I have just advanced, that, as we are a Council of Medical Education, and have much to connect us with her Majesty's Privy Council, it would henceforth be more expedient and proper that we should seek the assistance of the Lord President of the Privy Council to introduce any Bill into the House of Lords, rather than again fruitlessly seek the assistance of the overworked Secretary of State for the Home Department in the House of Commons.

THE COLONIAL PRACTITIONERS' ACT.

I must next say a few words upon an Act of Parliament recently passed termed "An Act to amend the law relating to Medical Practitioners in the Colonies." Prior to the introduction of this Bill into the House of Lords by the Duke of Buckingham, there was forwarded to me by direction of Mr. Hardy various documents relating to it, and I was requested to peruse them, and return them with my opinion upon them. Having read them, I fortunately had the opportunity of conferring with the Executive Committee before I wrote my reply to the Home Secretary's communication. I made various suggestions in reference to the proposed legislation in my letters, which I now place on the table, because it has not before been brought under your notice.

When the Duke of Buckingham proceeded with his Bill, I found that all my suggestions contained in the letter to the Home Office had been entirely ignored. I therefore immediately applied for an interview with the Colonial Secretary, and this being granted, Dr. Sharpey and Mr. Hawkins kindly accompanied me to the Colonial Office. When offering our objections to the Medical Practitioners (Colonial) Bill, I adverted to my letter, as President of this Council, on the subject, when his Grace informed us that he had never seen nor heard of any such letter from the President of the Medical Council; in truth, it had never been transmitted to his Grace from the Home Office. Fortunately, I was provided with a copy of the letter, which I then read to the Duke, and left it with him. The result was the objectionable parts of the original Bill were amended, and the measure has now passed in a form to which little objection can be made.

THE REPRESENTATION OF THE PRACTITIONER ON THE COUNCIL.

There is one other topic to which I may briefly allude before I sit down, and that is the prospect there is of your being invited to look into your own constitution, and decide whether you think that constitution would be improved by an increase of your number and by the introduction of members who are to represent interests, which it is alleged by some persons are not duly represented in the Council. It could hardly be expected in this era of radical reforms and organic change in the Legislature, that this Council, which has hitherto been regarded as fairly representing the profession for those purposes for which it was constituted, should remain undisturbed and that attempts would not be made to alter its constitution and character. I am sure I am expressing the sentiments of all when I say, that whenever this question is properly brought before us, we shall be prepared to give a patient, careful, candid, and temperate consideration to the argument and reasons by which such a proposal is supported.

Lastly, it is a duty which I owe to the members of the Council to remind them of a circumstance to which I have already alluded, that my term of office as President will probably have expired before the next annual session of the Council. Now it is all essential to the future harmony and credit and good working of the Council that this question of the election of my successor to the honourable and distinguished office of President should not take you by surprise. You will during the present session have frequent opportunities of personal intercourse, and I trust you will make that one of the topics of private, friendly discourse—it can hardly be discussed in public. Then as to the precise date when I should vacate my office? Whatever course may most contribute to the convenience of the Council, and be most conducive to uphold the dignity and honour of the office, will be the most acceptable to my feelings.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 1, 1868.

FORTITER IN RE.

THE profession will scarcely be reassured, albeit their faith in the Medical Council needs strengthening, by the pitiable exhibition of timidity and irresolution with which the exercise of their very simple power of removing a person from the register for "infamous conduct in a professional respect" was attended last week. The desire to suppress public discussion of their act by obstructing the record of their proceedings in the public journals, was worthy of the subsequent proceedings, and indicated a very reasonable apprehension that the proceedings of some members would not be read to the credit of the Council at large, or inspire confidence in its energy or boldness of action. We can hardly imagine the circumstances which should render a debate after investigation as to the truth of the charges at all necessary, much less can we understand what the peculiarities of the discussion might be which require that the thing should be "done in a corner." But the sequel explains all.

On the question, which to an earnest reformer would appear to admit of only one solution, whether a person, who under the false pretence of a special commission engaged in the sale of fraudulent diplomas, was deserving of being expelled from the profession, nine members of the Council supported the policy of pusillanimity, and four, scarcely less timid, declined to vote at all.

Our Special Reporter describes the scene as follows :—

"Upon this case opinion seemed to be equally divided, for when the motion of his expulsion from the profession was put to the vote, nine voted for and the same number against, the President giving the casting vote for his expulsion, whilst a few cautious members abstained from speaking or voting upon the question altogether, it being suggested by one or two speakers that the Council might find itself embroiled in some very serious legal difficulties, if they attempted to deal summarily with the accused. Some very plain-speaking followed as a necessary consequence, and for two hours the changes were very merrily rung on both sides. As, however, we have not space for the whole, and had we, some members who, as we have said, spoke in no very guarded language, might possibly object to their remarks appearing in print, we purposely omit further reference to the subject."

We cannot conceive a duty more plain or a function more secure than that of purging the profession of such gross practices. In its discharge the Council would receive the support and approbation of the entire profession, and the attempt to escape from the courageous performance of their functions by the suppression of publicity is a melancholy forecast for the future of professional reform.

Why did not the Council crown the absurdity by issuing a "recommendation?"

NOTES ON THE ABYSSINIANS.

No. III.

There is much that is peculiar and interesting in the Deaths and Funerals of the Abyssinians, whose religious tenets are so remarkable that Pontius Pilate figures as a Saint in their Kalendar.

When a sick person is not expected to live a priest is sent for, and he, among other duties, has to remind the dying man to declare his last wishes respecting the disposal of his property. These are not written, but, being simply declared in the presence of the priest and other witnesses, are taken for and esteemed his "last Will and Testament."

The funeral takes place on the day of death, and is thus described by Mr. Parkyns :—

> "All the priests from the neighbouring church assemble, and the relations of the deceased call from the house-tops and send messengers to the neighbouring villages, where, standing on eminences, they summon the neighbours by crying aloud, 'Such a one, son or daughter, of such a one, is dead. Come ye to the funeral, and bring the crosses and the incense bowls.' The priests on their arrival commence chanting the prayers, while the spectators weep and wail. The body, having been properly washed and laid out, is wrapped in a cotton shroud, with the face covered. It is then placed on a couch, upon which it is to be carried to the burial-place ; but before the procession is formed the body is removed to the outside of the door, and, on being again raised on the shoulders of the bearers, every one present who has a gun discharges it as a salute. The funeral train then sets out, the friends of the deceased who accompany it wailing and violently rubbing their foreheads and faces with the borders of their garments held in both hands. On its way to the church the procession makes seven halts, at each of which incense is burned over the body, and the priests and scribes read and pray. The service comprises the whole of the Psalms, which are read very quickly, a great number of the scribes as well as priests being present ; to each of these is allotted a psalm or two, and they all read their respective parts at the same time. In Abyssinia they have a hundred and fifty-one psalms, the extra one being merely a private history of David's youth, which it would appear we do not allow to be authentic. Besides the Psalms they read certain portions of the New Testament. The seventh halt is made at the church gate. Should, however, the dead person's house be near the church, five of the services are read previously to starting, and only the remaining two on the road. The mourners usually take care to have among their party some friend learned in such matters, to prevent their being cheated out of any part of the reading. The corpse is carried by the friends in turn. On entering the church another long service for the dead is performed, at the conclusion of which the priests wrap the body in a mat, made of the leaves of the date-palm, as symbolical of the branches of the palm which were spread before our Saviour on his entering into Jerusalem—death being considered as the entry of the Christian to the spiritual Jerusalem."

In Abyssinia there are no professional grave-diggers; but while the funeral proceeds, as already described, any one present lends a hand, and helps to inter the deceased, in pursuance of the popular opinion that it is a meritorious and charitable act to bury the dead. When the grave is prepared, the priest descends into it and perfumes it with incense, after which the body is lowered to its last earthly resting-place. At various intervals of days masses are said for the deceased, and are accompanied by some extraordinary proceedings on the part of the near relatives. On the day of the chief or high mourning, the third after death, the relatives, both male and female, publicly signify their sorrow by shaving their heads ; and they rub themselves so severely on the forehead and temples as to abrade the skin completely, and produce a sore which takes a long time to cure ; and even when healed, the part remains for some time as white as a European's skin. By degrees, however, it assumes a darker colour, and at last becomes even blacker than the rest of the face ; but in all cases a mark is apparent for several years, and frequently for life. The custom of crying or singing (*Hibernicè* "keening") is also common at funerals ; and there are paid professional women, "keeners" as in Ireland, who act as a choir, and improvise verses in praise of the deceased, who, we presume, is lauded whether he deserved it or not, according to the charitable maxim, *nil de mortuis nisi bonum.*

Owing to the extreme ignorance of the natives about medicine, and to the custom of burying within a few hours of the presumed death, it often happens that people are buried alive in Abyssinia. Mr. Parkyns relates that during a funeral it is not rare to hear noises emanating from the freshly filled tomb. These are often attributed to the "Booda," or Evil Spirit making off with the body, and no one would think of re-opening the grave to examine into such cases, which are caused generally by burial during life.

Another custom of which this people are ignorantly guilty is that of howling at the bedside of a sick relative. A case in point is thus related by Mr. Parkyns :—

> "A servant of mine was once dangerously ill, of which, however, I was not aware, no one having intimated to me the extent of his complaint ; and as they seemed to prefer doctoring him themselves, I had only inquired after him casually when passing his hut, thinking that little was the matter, till one day I was astounded on hearing the death-wail raised where he was lying. On immediately hastening to see what was the matter, I found that though he was seriously ill he was neither dead nor dying. The effects of a violent fever had rendered his head shaky ; and, though not delirious, he was wandering, and when I spoke to him he muttered something, of which the only intelligible word was 'death.' To afford him momentary relief I had him sponged all over, and gave him some medicine ; after which he became a little more sensible, but still continued to speak of his death. I expostulated with his father about the wailing, and on his ordering the women off I went and sat with the lad, and by keeping him cool and easy by sponging, and continuing to talk to him cheerfully, I at last persuaded him that there was nothing seriously the matter. The result was, that he gradually got better ; though I firmly believe, that, had the women been allowed to have their way, they would literally have howled him to death."

We must not omit to notice that intoxication is a frequent, even a general, accompaniment of Abyssinian funerals; which in this, as in other particulars, are strangely like the typical festive funeral gatherings of the Irish peasantry, who often eat, drink, cry, sing, pray, and are merry, when sorrowing for the loss of people whom they never saw once when alive.

Notes on Current Topics.

The Carmichael Prizes.

We understand that the Council of the Royal College of Surgeons of Ireland, inasmuch as the bequest of the late Mr. Carmichael for the purposes of the prizes was, under certain contingencies, to pass to the Royal Medical Benevolent Fund Society of Ireland, has taken the opinion of the Right Hon. J. A. Lawson as to the legality of the acts of the Council in respect of the adjudication of the prizes. The reply of the learned gentleman was lately laid before counsel, and, as we learn, completely justifies the action of the Council in the matter. Mr. Lawson is of opinion that Dr. Mapother, though a councillor, was perfectly eligible to seek and receive the prize; that it was competent for the Council to appoint a committee from themselves to adjudicate, and to vote any reasonable remuneration to the members of that committee for their services. Mr. Lawson advises that the Council, having advertised prizes of £200 and £100, and the candidates having sent in their essays on the faith of such advertisement, the Council ought not on this occasion to avail themselves of their powers to increase the grant to £400 and £200.

The Next Army Examination.

We are enabled to state that the number of vacancies for assistant-surgeoncies in her Majesty's army for the examination next August, will be smaller than usual. It is expected that they will not exceed twenty-two.

Public Prosecutors.

A good deal has been written in favour of appointing such officers in England. Yet in Scotland they do not give universal satisfaction, if we may judge from a remark of Dr. Alexander Wood's in the Medical Council last week. He observed that a certain person had not been prosecuted, because in Scotland it was necessary to apply to the Public Official, who could refuse to do anything, whereas, in England any one so disposed could commence a prosecution.

Convenient Indispositions.

For the credit of our profession, we most earnestly trust that our brethren will be warned by the contemptuous rejection of Sir W. Fergusson's certificate of the illness of Madame Rachel by the sitting magistrate.

We certainly do not believe that any greater fault is attributable to the learned baronet than haste and thoughtlessness in acting inadvisedly on false representation; but we would have our brethren more cautious than they appear to be in guarding against such indiscriminate certifying.

The New Anæsthetic.

The use of the cumbersome apparatus for the manufacture and storage of nitrous oxide, which we described in our last as in use at the metropolitan hospitals, has been obviated as regards the employment of the anæsthetic in private practice by Mr. Barth, of London, who sells the gas compressed into bottles, with a suitable valve, by means of which it can be made available in all cases to which its employment is suitable.

The New Penny Paper on the Public Health.

We are glad to observe that the *Daily News*, the enlightened organ of the more thoughtful advanced Liberals, which always evinced considerable interest in matters of this kind, does not seem disposed to neglect them, now that it has reduced its price. A high-class Liberal paper, that would devote fair space to matters medical and be above all partiality, would secure the support of the profession. We give an extract from the *Daily News* of Thursday last :—

> "Nothing tries the health of great cities like hot and dry weather. It is in the most brilliant sunshine that epidemics fester. The great year of the plague was a year of blazing summer, and the cholera seasons of the present century were all hot, and in their worst weeks dry. It is therefore satisfactory to know that the hot dry weather which has just been broken by these summer showers has left the health of London remarkably good. The deaths from zymotic diseases are under the average, and even those from diarrhœa, the disease almost peculiar to summer, were comparatively few. But we owe this favourable condition of the public health almost entirely to the sanitary improvements of late years, and we can only maintain it by watchfulness. Hot weather will always bring choleraic diarrhœa, and the number of persons attacked will rise as the thermometer rises. This, therefore, is a most inopportune time for reducing the sanitary staff of any metropolitan parish, much more of an East-end parish. For the next three months sanitary inspection is more useful and more needful than at any other period of the year. Let this sweet summer air be poisoned by bad smells from choked-up drains and it becomes all the deadlier from its very warmth and softness. Yet the registrar tells us that the parish of Whitechapel has just reduced its staff of inspectors of nuisances. Is this an indication of any diminution of inspection, or any relaxation in the watchfulness of the parochial authorities over the public health ? If so, its results are certain to be bad, and may possibly be disastrous. But here is only another illustration of the divided and cumbrous nature of our metropolitan administration. The health of any and every parish in this vast city is not merely its own concern, but is the concern of all the rest. Disease seizes on the least protected part, but getting a vantage ground there it assails the whole. Our present system puts on the parishes which because they are the poorest, need the most inspection, all the cost of a carefulness which is of immense importance to us all. The inspectors of nuisances in the East-end should be borne equally by West and East, for they are needful for the protection of both. Happily, in the present season, there is no epidemic in the air, and no poison in the water. We have got thus far into a sultry summer with unusual healthfulness, and with even ordinary care against defilement of the vital air, or of the almost equally vital water, we may hope that 1868 will not only be a year of plenty but a year of health."

The delays of the law have operated in the adjournment of the case of Eastlake *v.* Edmunds to the next term.

◆

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

Royal College of Physicians, London.

Wednesday, June 24, 1868.

Dr. Burrows, President, in the chair.

Present.—Dr. Bennett, Mr. Hawkins, Mr. Cooper, Dr. Acland, Dr. Paget, Dr. Embleton, Dr. Storrar, Dr. Alexander Wood, Dr. Andrew Wood, Dr. Fleming, Dr. Syme, Dr. Thomson, Dr. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Sir D. Corrigan, Bart.; Dr. Sharpey, Dr. Parkes, Dr. Quain, Dr. Rumsey, Dr. Francis Hawkins, Registrar.

The President then delivered his Address, which will be found at page 9.

A letter was read from the Secretary of British Medical Association to the effect that—

"The Committee of Council of the British Medical Association had appointed a deputation to wait upon the Medical Council in reference to the further representation of the profession in the Council, and requesting an audience."

Tuesday (yesterday) was fixed.

The following motions were then passed with but little discussion :—

"That the reference from the Scottish Branch Council on the subject of Lunacy Certificates be referred to a Committee who shall consider the subject, in concert with Mr. Ouvry, the Council's solicitor, and report to the Council."

"That the letter from the Medical Department of the Privy Council of November 28, 1867, together with the letters from the various Licensing Bodies connected with the subject of Vaccination, be referred to a Committee, to draw up for the approval of the General Council an answer to the Privy Council."

"That the observations of the Licensing Bodies upon the Report of the Committee of the Medical Council on the Visitations of Examinations be received and entered on the minutes."

"That the Reports of Visitations since the last meeting of the Medical Council be received and entered on the minutes."

"That a Committee be appointed to consider the observations and the reports of visitations of examinations, referred to in the two last resolutions, and to report thereon to the Council."

"That the Returns from the Army and Navy Medical Departments, and from the India Office, relative to the Examination of Candidates for Commissions in the respective services, be received and entered on the minutes."

We are compelled to postpone the publication of the important returns from the Army Medical Department.

NAVAL MEDICAL SERVICE.

"Admiralty, Somerset House, April 24, 1868.

"SIR—We have the honour to acquaint you for the information of the General Council of Medical Education and Registration, that, during the year 1867, thirty-five candidates presented themselves for examination for medical commissions in her Majesty's naval service; but that of these, three, who were rejected on their first examination, presented themselves a second time, so that thirty-eight examinations altogether were held.

"2. The result of these examinations was that in twenty-seven instances the answers given were of a more or less satisfactory character, and the candidates were admitted into the service; in ten they were unsatisfactory, and the candidates were accordingly rejected; and one candidate was found to be physically unfit for the service.

"3. In three of the twenty-seven successful examinations the answers were very good in all branches; in thirteen, good; in nine, fair only; and in two, indifferent.

"4. Two candidates who passed good examinations, and one a fair examination, had been previously rejected during the year; and one who passed a very good examination in all branches, and one a fair examination, had been rejected during the preceding year.

"5. Appended hereto (for which we have not space this week) are lists of the subjects upon which the candidates were orally examined; the questions forming the subjects for their written examinations; and a tabular statement showing the qualifications of the different candidates, according to Schedule (A) of the Medical Act; the results of the examinations in each case; and the subjects on which the candidates were most deficient.

"6. In consequence of the preliminary examinations now instituted by all licensing bodies in accordance with the recommendation of the General Medical Council, their lordships were pleased to direct that, in future, the examination in Latin by candidates for naval medical commissions should not be compulsory. This regulation came into force on the 7th of May, 1867.

"7. We are of opinion that the examinations on the professional subjects have not evinced any marked superiority over those of the preceding year; and we find in the candidates an increasing disinclination to be examined in Latin, and that few of them possess a useful knowledge of that language.—We have the honour to be, sir, your most obedient servants,

"JAS. SALMON, Deputy Inspector-General, R.N.
"WM. R. E. SMART, M.D., Dep. Inspector-Gen., R.N.
"ALEX. E. MACKAY, M.D., Dep. Inspector-Gen., R.N.
"J. D. MACDONALD, M.D., F.R.S., Staff Surgeon, R.N.

"Dr. Bryson, C.B., F.R.S., &c.,
Director-General, &c."

REGISTRATION OF COLONIAL DEGREES.

A letter from the Chancellor of the University of Melbourne to the Home Secretary, preceded by one from the Colonial and one from the Home Office, drawing the attention of the Council thereto, was then read, from which we extract the following:—

"There is doubtless much force in the suggestion that those charged with the grave responsibility of admitting to registration applicants who arrive in England from distant countries, should be allowed full opportunity to satisfy themselves as to the respectability and social standing of such applicants. Nevertheless, I may be allowed to submit, with great deference, the compulsory residence in England, for the period of one year, previous to the application, is not required; for it is quite possible to make provision that such persons may apply to be registered in England, on producing to the General Council a certificate or certificates of the nature deemed necessary, signed by the Governor,

"The Chief Justice,

"The head of the religious body to which the applicant belongs,

"The principal medical officer of the colony, or any of the chief officers of State, together with the like certificate or letters discussory or recommendatory signed by the Chancellor, Vice-Chancellor, Warden, or Principal, or the representatives of those officers, and six members, at the least, of the University in which he has taken a degree.

"Thus, should a medical man possessing a degree confirmed by the University of Melbourne, present himself for registration in London without the prescribed Certificates, or should it be necessary to refer to the proper authorities in this country to complete any portion of the evidence requisite, a period of six months would amply suffice to procure all required, while any further delay could form no grounds for just complaint, as it would be attributed in all likelihood to some inattention on the part of the applicant, whose duty it would be to furnish all the testimony required by the Act.

"I trust you will permit me therefore to impress upon you, that you be pleased not to insist on any compulsory residence in England before registration by any of the Medical Graduates who may arrive in the United Kingdom furnished with the Certificates or other testimony mentioned above.

It was then moved by Dr. SYME; seconded by Dr. RUMSEY, and agreed to:—

"That the communication be entered on the minutes."

Sir DOMINIC CORRIGAN suggesting that a copy of the Duke of Buckingham's Colonial Degrees Bill, now before Parliament, should if possible be laid before the Council at the same time.

COMMITTEES ON THE "HOW, WHEN, AND WHERE" OF MEDICAL EDUCATION.

On rising to move the following motion, which was seconded by Dr. ANDREW WOOD:—

"That a committee be appointed to consider and report how the various subjects of medical education which have been deemed requisite by the Council may be taught with most advantage; in what order they should be studied; and how the examinations on them ought to be arranged,"

Professor SYME, whose remarks were very inaudible, was understood to say that he felt greatly impressed with the importance of the subject with which he had to deal, and was almost constrained to apologise that it was not in abler hands. As a teacher and examiner for forty years he could, however, speak with some degree of certainty. He knew great diversity of opinion existed both in the Council and beyond the pale of its constitution, as to the best means to be employed in educating the youth for the profession; hence his proposition shaped itself into three distinct clauses. *How* it could best be done; in *what order* it should be pursued, and *when* the examination should take place. There were two great errors prevalent with regard to teaching. One was that teaching implied learning, and that learning was the same as committing to memory. The act of learning, or acquiring new ideas, was an act of the mind, no less essential for the purpose than the acts of digestion and assimilation were for the adaptation of nutriment to the body; and they could no more make a man learn by the mere enunciation of facts and opinions than they could make a man strong by distending his stomach with food. Nevertheless, many teachers, forgetful of this, believed that they discharged their duty by pouring forth volumes of details, no sooner received than forgotten. A man might be a profound scholar and yet a bad teacher. He considered the system adopted in Scotland superior to that in any other part of the kingdom. There they had but three medical schools; but in London and Dublin almost every hospital had its school, as well as nearly all the large provincial towns, and this he conceived was in some measure the cause of the present unsatisfactory state of things. With so many schools, it caused the number of students to be distributed over a large area; and from his experience it was much easier and much more satisfactory to the teacher, to have a large class than a small one. He thought teachers now looked upon their appointment to one of these schools as a something that suited their present purpose—a stepping-stone to a future appointment that would bring them in a much heavier emolument. He would abolish all these minor schools and limit the number to a few of the larger ones, as in Scotland, and he then believed we should get more competent professors and teachers—men who would look upon teaching as an honour worth seeking, and when obtained to be held for the best of their life.

Dr. ANDREW WOOD had great pleasure in seconding this motion, as he anticipated some good must result from a free discussion thereon. If Professor Syme was right, Dr. Parkes's scheme of education must be wrong; there were points in both he was not prepared to endorse, he hoped after due consideration they would be able to reconcile the two seemingly opposite schemes, and draw therefrom one which would be generally acceptable. He would suggest that they should have all the medical teachers in the kingdom before them, and endeavour to arrive at the right and wrong sides of the question; with such evidence before them, he thought such a system might be adopted, as would redound to the credit of the proposer and the Council also.

Sir **Dominic Corrigan** begged to propose the following amendment, seconded by Dr. **Storrar**:—

"That a Committee be appointed to consider and report in what order the various subjects of Medical Education which have been deemed requisite by the Council may be taught with most advantage, and how the examinations on them ought to be arranged."

Sir Dominic argued against the concentration of schools proposed by Professor Syme, and said he considered the competition by the many was productive of great good, both as regarded the status of the teachers, and the anxiety of students to be at the top of the tree. Competition was the order of the day, if we did away with it, the standard of education would be lowered, and emulation, which was the basis of all knowledge, would soon cease to exist. Students under the present code, went where it was most convenient, and where they could get best value for their money, but if the proposed concentration took effect they would be compelled to go to these one or two schools, because they could not obtain the necessary instruction elsewhere. He also disagreed with Professor Syme that large classes were easier to teach than small ones. He had never found it possible to teach, clinical medicine and surgery, properly to large numbers; he thought teaching would be more successful if each subject were brought under the individual attention of students—take them to the bedside, and let them see facts for themselves; a mere knowledge of words, from ever so good a teacher, when a large number were arranged round a class-room, added to all the cramming a professional grinder could impart, would not be nearly so satisfactory. He would make the examination what it ought to be—thoroughly practicable. He was also opposed to the suggestion thrown out by Dr. Andrew Wood—"That all the medical teachers in the kingdom should be summoned before the Council;" he did not think that possible, in fact, with such a multitude of councillors and their evidence to deal with, the members of that board would soon be *non est*."

Thursday, June 24.

The debate on Professor Syme's resolution was resumed by Dr. **Parkes**, who regretted that some portions of his recent pamphlet on Education had been misinterpreted. He was, however, pleased to find that the scheme as propounded by Professor Syme, and that contained in his pamphlet, though at first sight they appeared to clash, on close examination the difference was very slight. He said the term of "wet nurse" had been applied to his proposition, and he would accept the definition as a compliment, because he held that when students came from school they were, as far as science was concerned, but children, and what better mental food could be given them than that which should minister to the growth and vigour of the mind. Even Professor Syme, like every other practical teacher, must of necessity proceed from particulars to generalities. He entirely disagreed with the amendment of, and the doctrine as put forth by Sir Dominic Corrigan on the previous day; it appeared to him that if the amendment were adopted the pith and marrow of all that was good in the original proposition would be left out, and he would rather do away with the whole question than vote for the amendment. He entirely coincided with Professor Syme, that a committee should be appointed to take the whole matter into consideration; let them at least try what could be done, let them court the opinions of those teachers most competent to give them, let objections come whence they might, and he did not despair that the committee would be able to bring up a report, upon which the council could base all future legislation.

Dr. **Allen Thomson** thought the time was come when a revision of the existing clauses was absolutely necessary; it was a fact that the profession and the public at large looked anxiously to the Council for deliverance from the existing anomalies. Several branches could be improved, others could be entirely remodelled, whilst those which had proved useless could be left out altogether. He instanced chemistry in the preparatory branch, in the form now taught it was very undesirable; in fact, in its application to medicine, was perfectly valueless.

Dr. **Sharpey** feared it was scarcely possible that the Council could arrive at a very congruous conclusion on the subject before them, still he hoped they might, by careful deliberation, improve the existing educational code, so as to make it more generally acceptable.

Dr. **Aquilla Smith** would support the resolution of Professor Syme, as it was less restrictive than the amendment; he considered it impossible that any fixed rules could be laid down for teachers, because what would be applicable in one case would not be in another.

CASE OF DR. MACDONALD.

It being three o'clock, the time appointed to consider the case of Dr. William Macdonald, who was summoned to appear before the Council at this hour, the debate on Mr. Syme's resolution was adjourned.

The **President** then rose to suggest that, as the case before them was of a very serious nature, and the character of one of their professional brethren was at stake; and as, moreover, matters of private import would necessarily be introduced into the discussion, he deemed it advisable that the reporters be requested to withdraw.

Whereupon a long discussion arose, in which almost every member took part, the majority contending that, as that was essentially a court of justice, and as, in such courts, there was no precedent of the press being excluded, exception should not be taken in this instance, unless their legal adviser, who was present, should show them that there was any illegality in discussing the subject in public.

Mr. **Ouvry** then read the sections bearing on the point, and considered that it was within the province of the Council to deliberate on any one point of the evidence either in public or private.

A motion was then put by Mr. **Hargrave**, seconded by Dr. **Rumsey**—

"That the reporters be requested to withdraw."

This motion was lost by a very large majority.

A letter from the Registrar to Dr. William Macdonald, was then read, to the effect that a statement had been made that he had been guilty of infamous conduct in a professional respect:—

"First.—In offering to procure for fee or reward, the Degree of Doctor of Medicine from Pennsylvania College.

"Second.—In offering to procure for fee or reward the Degree of Doctor of Medicine from the University of Giessen.

"Third.—In falsely pretending to hold a Commission from the said University of Giessen, for inviting young persons, aspirants for the Degree of Doctor of Medicine, to Giessen."

Dr. Macdonald not being in attendance, and having declined to appear before the Council, Mr. Ouvry then read at full length the evidence in support of the charges, and also the answers to them which Dr. Macdonald had addressed to the Council as his defence.

Upon this case opinion seemed to be equally divided, for when the motion of his expulsion from the profession was put to the vote, nine voted for and the same number against; the President giving the casting vote for his expulsion, whilst a few cautious members abstained from speaking or voting upon the question altogether, it being suggested by one or two speakers, that the Council might find itself embroiled in some very serious legal difficulties, if they attempted to deal summarily with the accused. Some very plain speaking followed as a necessary consequence, and for two hours the changes were very merrily rung on both sides. As, however, we have not space for the whole, and had we, some members who, as we have said, spoke in no very guarded language, might possibly object to their remarks appearing in print, we purposely omit further reference to the subject.

It was ultimately moved by Mr. **Syme**, seconded by Dr. **Fleming**—

"That William Macdonald, of Ewing-place, 359, Argyle-street, Glasgow, M.D. Univ. Edin., 1830; Fel. Fac. Phys. Surg. Glasgow, 1832, is judged by this Council, after due inquiry, to have been guilty of infamous conduct in a professional respect."

Amendment moved by Sir **Dominic Corrigan**, and seconded by Dr. **Apjohn**:

"That the General Medical Council, however disapproving of Dr. Macdonald's conduct, is of opinion that the case before them is one in which it is the province of the Universities which deny that Dr. Macdonald was authorized to act for them, to proceed against him, should they see fit, and not for the judgment or intervention of this Council."

The amendment was negatived.

The original motion was then put to the vote and carried.

Sir **Dominic Corrigan** required that the names and numbers of those who voted for and against the motion, and of those who declined to vote, should be taken down.

Majority, 10—The President, Dr Bennett; Mr Hawkins, Mr Cooper, Dr Paget, Dr Alexander Wood, Dr Andrew Wood, Dr Fleming, Mr Syme, Dr Parkes.

Minority, 9—Dr Embleton, Dr Storrar, Dr Thomson, Dr A. Smith, Mr Hargrave, Dr Leet, Dr Apjohn, Sir D. Corrigan, Dr Sharpey.

Declined to vote—Dr Acland, Dr Quain, Dr Rumsey, Dr Stokes.

Moved by Mr **Syme**, seconded by Dr **Fleming**, and agreed to:

"That William Macdonald, M.D., having been judged by this General Council, after due inquiry, to have been guilty of infamous conduct in a professional respect, the General Council do hereby adjudge that the name of the said William Macdonald be erased from the register; and do by this order direct the registrar to erase his name from the register accordingly."

Dr. **Andrew Wood** required that the names and numbers of those who voted for and against the motion, and of those who declined to vote, should be taken down.

Majority, 12—The President, Dr Bennett, Mr Cooper, Dr Acland, Dr Paget, Dr Alexander Wood, Dr Andrew Wood, Dr Fleming, Mr Syme, Dr Parkes, Dr Quain, Dr Stokes.

Minority, 7—Dr Embleton, Dr Storrar, Dr A. Smith, Mr Hargrave, Dr Leet, Sir D. Corrigan, Dr Sharpey.

Declined to vote—Dr Thomson, Dr Apjohn, Dr Rumsey.

Moved by Mr **Syme**, seconded by Dr **Fleming**, and agreed to:

"That a copy of these orders, signed by the President in the chair, and countersigned by the registrar, be transmitted to the said William Macdonald, M.D."

MR. SYME'S MOTION.

The adjourned debate upon Mr. Syme's motion was then resumed by Dr. **Storrar**, who wished to state briefly why he had seconded the amendment of Sir Dominic Corrigan. In the first place he doubted if it was within the province of the Council to issue any prescribed rules, and to say to teachers that such and such should be the order, and that certain causes must be taught, whether their discretion told them it was right or wrong. That he considered to be a complete system of tyranny, and the sooner abolished the better. He would take his stand on the ground of liberty of teaching and liberty of learning. He conceived it to be monstrous that a student should be required to attend a certain number of lectures in the course of each term, and as it often happened, on subjects that were perfectly useless in the department of practice they intended to shape their course, and, as was frequently the case, the lecturer was thoroughly incompetent to the task, and indulged his class with readings—sometimes inaudible—from books that were useless in the present age. And he could not help saying that students could spend this hour—the torture of which they compelled them to undergo—much more profitably by study at their own firesides. The course proposed to the Council would in effect tie up the whole system of medical education. He would get rid of the intolerable system of lectures, and adopt one of drill, and of text-books—so that the raw student going in at one end of the machine should come out an educated one at the other. A very eminent authority—Mr. Simon—recommended that they should get rid of regulations altogether, so that if a man who presented himself was found fit, he should be passed whether he had gone through the prescribed formula or not. He considered the scheme before them of the wildest conception; if they chose to give a young man just a skeleton outline of the order of study well and good; but to fix a precise mode for every teacher to impart to his class the knowledge he possessed was simply absurd. He would recommend that the question be dealt with by the Examining Boards, or still better, by the Schools—the governing bodies of which would, if a certain amount of elasticity were allowed them for existing differences, turn out men much better prepared to enter upon the career they had chosen, than if the council adopted the restrictive policy of the proposed resolution. In the cause of freedom of education, therefore, he would support the amendment.

Dr. **Acland** said although he would support the motion of Professor Syme, confessed his entire concurrence in some of the remarks that had fallen from Dr. Storrar; although he did not believe with that gentleman, that the existing educational fabric was likely to tumble, he nevertheless maintained that much might be done to improve it; one of the first steps towards which would be, that they should dictate only such a course as was absolutely necessary; that students should not be compelled to attend certain lectures, or have their brains crammed with subjects that would never be of use to them in practice. He was therefore pleased that the subject which he had brought before the Council some four years since, and which then seemed distasteful to the majority, was now likely to go before a committee, from whom he anticipated a solution of the difficulty which, in the present condition of opinion on the matter of education, cried for reform. It being six o'clock the debate was again adjourned.

Friday, June 26.

After the minutes of the previous day had been read, Dr. **Risdon Bennett** proceeded in a lengthy speech to criticise the arguments adduced on both sides during the two previous days' debate, on the motion brought forward by Professor Syme. Although it was desirable to get through the business of the session as speedily as possible, still on so important a question as that before them, every member should have the opportunity of speaking, before giving a silent vote. Nothing in his mind was more important than they should give out what was necessary for the student to learn, and should see that the licensing bodies taught the various subjects in accordance with their recommendation. Opinions had been expressed that the Council were either incompetent to deal with the subject, or were reluctant to interfere with existing arrangements, or that the difficulties surrounding it were insuperable, and that therefore it was left without an attempt being made to alter it. There might be some truth in the remarks that were constantly made use of out of doors; for undoubtedly a grave responsibility hung around the subject, but the time had now arrived that they should face the difficulties; so that no grounds of complaint should be left as to their inability, or incompetence to interfere. He agreed with several speakers that there were great differences of opinion, but if it were grappled with, he doubted not that the committee, if appointed, would receive ready assistance from all quarters, from those teachers most competent to give it. He regretted so much time and attention had been given to the pamphlet by Dr. Parkes—not because he did not consider it a very valuable production, on the contrary, but because the minds of the Council were thereby more or less prejudiced by a book, which after all, was but the opinion of one man, although he would readily admit from the eminent position occupied by Dr. Parkes, no one was probably better able to give it than he. If he understood the proposition aright, the question was simply how the various subjects deemed necessary for the acquirement of professional skill and knowledge, could best be taught. The proposition was of great value, one which he hoped the Council would consider of paramount importance, and while admitting it to be impossible that one particular mode of teaching could be adopted by every teacher under all circumstances, yet if a distinct understanding were not at once come to, he feared they would merit the blame that had been constantly heaped upon them out of doors.

Dr. **Paget** was of the same opinion, and thought that the expressions of the Council should not go forth as regulations to be devoutly observed, but in the form of recommendations, or suggestions, or if they chose, merely as expressions of opinion to serve as a guide to those engaged in medical tuition.

Mr. **Cæsar Hawkins** would support the amendment of Sir Dominic Corrigan, and suggested that a certain amount of levity should be allowed to teachers, as they had to consider not only the abilities of these, but the minds of the pupils also. He agreed with one or two speakers that if they attempted to enforce tuition by certain rules, they would certainly be unsuccessful.

Dr. **Embleton** opined that if a committee were appointed, it would at once become a nucleus round which to gather some very valuable information; he hoped the scheme would be at once broad and comprehensive, that it should be neither too much English, Irish, or Scotch, but thoroughly British in all its bearings. He would further suggest that a time be specified when the report of this committee should be ready, and that every member of the Council should be furnishe with ad-copy thereof, before their next meeting, so as to be fully prepared to deal with the whole subject.

Dr. **Stokes** considered that the speeches at the present juncture, might be taken as an evidence of what was passing in the minds of the Council generally. He agreed with Dr. Storrar that a line should be indicated but not enforced. Coercion might be necessary in subjects that could only be taught by demonstration, because the student could not possibly have the various apparatus—such as the dead body, &c., in his own rooms; but coercion should be entirely limited to such subjects which must of necessity be demonstrative. He thought Mr. Syme had spoken very severely of the tutorial system. The tutorial system and the system of grinding or craming was essentially different. The former sought to instil into the pupil's mind, that it was not so necessary to learn a prescribed number of subjects for a particular end; but it endeavoured to impress upon his mind how he could teach himself; whereas the latter endeavoured to fill his mind with a smattering of facts, which although upon the surface only, would enable him to answer the questions put in the regular examination.

Dr. **Quain** feared there was no probability of the Council being able to come to any definite resolution, or to agree to any particular course, if even they sought for information from the various licensing bodies; with so many diverse opinions he thought there was little chance of agreement, and could not therefore support the resolution before them. He was in favour of examination being the test of merit. If a student should acquit himself creditably of an examination which should be eminently practical, he would pass that man, no matter how or where he obtained the necessary knowledge, without requiring that he should produce a certificate of having attended this or that course of instruction or lectures.

Dr. **Fleming** argued that if they could find a committee in the Council who were willing to undertake so arduous a task as that proposed in Professor Syme's resolution, they were bound to accept it. It could at least do no harm, and might be productive of great good.

Mr. **Syme** replied to the criticisms his motion had provoked.

The amendment of Sir Dominic Corrigan was put to the vote, and lost by a majority of 13 to 7. Mr. Syme's original motion was then agreed to, and a committee appointed of the following members:—

The President, Dr. Parkes, Dr. Stokes, Mr. Hawkins, Dr. Sharpey, Dr Acland, Dr. Andrew Wood, Dr. Thomson, Dr. Smith, Dr. Christison, Dr. Apjohn, Mr. Syme, Mr. Hargrave.

The consideration of the communications to the Council from the Colonial Office, Home Office, and Chancellor of the University of Melbourne, were next taken into consideration.

Sir **Dominic Corrigan**, in rising to move "That the General Medical Council see no objection to the introduction of a clause in any amended Medical Act that may be introduced, providing that graduates in medicine of the University of Melbourne shall be entitled to register as medical practitioners in the United Kingdom on the production of the necessary proof of their having graduated in medicine in the University of Melbourne, and paying the fees payable on registration in the United Kingdom," saw no difficulty in granting so simple and so just a request. They all knew that the University of Melbourne stood very high in the estimation of men who were most competent to judge. Some of the most creditable graduates he had seen had taken their diplomas from this University, and he thought as the requirement that a graduate from the colonies should first reside in Great Britain for one year before he could be placed on the register emanated from the Home Office and not from the Council, the time had now passed when this should be a condition of his being allowed to practise his profession here, provided he could produce a certificate authoritatively signed and sealed by the governing body of the University in question. He was not afraid if the Council adopted this course, that any laxity would be shown in the granting of these certificates.

Dr. **Andrew Wood** would second this motion because he considered a great injustice had hitherto been done to the colonies, the graduates from many of the universities of which had proved themselves in every way worthy the privileges enjoyed by British subjects at home. He hoped the council would take advantage of the present application, to show the colonies that it was not only desirous of removing the injustice which had so long existed, but also of dealing liberally with them. Their was a great distinction between foreign and colonial universities, he would certainly not grant the same privileges to the former, and it was on these grounds he hoped the motion would be passed, as they were bound in justice to all the subjects of the British empire to remove any line of demarcation that might exist.

Dr. Alexander Wood, Dr. Paget, Mr. Hawkins, Dr. Acland, and other speakers, agreed that the graduates from the University of Melbourne reflected great credit upon its licensing body, but feared that if the condition of a year's residence in this country were removed in one case, a precedent would thereby be established, and the council would be immediately deluged with similar applications from every university in existence; and as there were some whose method of granting diplomas was so objectional that they could not possibly concede this privilege, complaints of injustice would be freely indulged in. Whilst, therefore, fully admitting the claims of the University of Melbourne worthy the most serious attention of the Council, they conceived it would be advisable to postpone immediate action to some more favourable occasion.

The following amendments were then put to the vote:—

Moved by Dr. **Sharpey**, and seconded by Mr. **Syme**:

"That in any provision which may be introduced into an amended Medical Act, for admitting to Registration persons holding Degrees or Licenses from the University of Melbourne, previous residence in England be not required as a condition of admission to such registration."

The amendment was carried, and then put as a Substantive Motion.

Moved by Mr. **Cæsar Hawkins**, and seconded by Mr. **Hargrave**:

"That in any provision which may be introduced into an Amended Medical Act, by which power would be given to Register Graduates of the University of Melbourne in the British Register, previous residence be not required as a condition of admission to such registration."

The amendment was then put as a Substantive Motion, and carried.

Moved by Dr. **Sharpey**; seconded by Mr. **Hawkins**; and agreed to:

"That the above resolution be communicated to the Secretary of State for the Home Department in reply to the letter of the Chancellor of the University of Melbourne."

Moved by Dr. **Alexander Wood**:

"That a Committee be appointed to consider the List of Bodies whose *Testamurs* are considered sufficient evidence of the student having received a competent Preliminary Education. That the Committee do also consider and report whether any plan could be devised, by which the Council could better supervise the Preliminary Examinations, or dispense with the necessity for frequent supervision, or in any other way promote the improvement of the General (preliminary) Education of the Medical Student."

This motion having been agreed to *nem con*, the Committee was appointed by the mover as follows:—Dr. Alexander Wood, Chairman; Dr. Fleming, Dr. Acland, Dr. Embleton, Dr. Rumsey, Dr. Leet, Dr. Storrar, Dr. Sharpey, and the meeting adjourned.

◆

THE MEETING OF LONDON AND PROVINCIAL POOR-LAW MEDICAL OFFICERS.

The aggregate meeting of London and Provincial Poor-law Medical Officers took place on the 24th inst., under the presidency of Mr. Clements, F.R.C.S., and M.P. for Shrewsbury. The following resolutions were adopted:—

"That this meeting is of opinion that it would be conducive to the best interests of the State that the Poor-law Board should consist of a definite number of responsible members; and, as the present arrangements for the treatment of the sick poor are unsatisfactory, that the control of all medical arrangements, including the fixing of the salaries of the medical officers, should be immediately subject to a special medical department."

"That this meeting is of opinion it is desirable that in the second article of the general order of the Poor-law Board, dated May 25th, 1857, the words referring to residence within the district be omitted; and that since the words 'or be removed by the said board' give unlimited, or at least too large a measure of arbitrary power to the said board, these words either be expunged or be altered to 'or be removed by the said board after a public inquiry, of which due notice shall be given.' And that some means be adopted to ensure the uniform carrying out of the general order so altered throughout the whole country."

"That it is desirable to insert clauses in the Poor Relief Bill now before Parliament—

"*(a)* To give effect to the opinion of the Poor-law Board that the providing of medicines by guardians is an expedient course.

"*(b)* To make Clause 38 of the Metropolitan Poor Act, 1867, compulsory on the Poor-law Board.

"*(c)* To enable the Poor-law Board to direct the formation of dispensary districts in the larger provincial towns, &c., as and when they shall think fit."

In the present crowded state of our columns, it is impossible to give a lengthy report of the proceedings, and postponement would be of little avail, as the General Medical Council is sitting, and its meetings must occupy much of our space. We, therefore, content ourselves with an abstract of the speeches of Mr. Clement, M.P., who, as chairman, lent valuable aid to the movement, and of Dr. Rogers, who laboured to get up the meeting, and himself took the first resolution.

The Chairman said that although the opposition of guardians and the indifference of the Central Board might be as great as ever, yet there was growing up a healthy public opinion which in time would work out good results both for themselves and the sick poor. Regarding a better treatment of the sick poor as a question above party, men of all shades of political opinion had united in pressing upon the legislature the necessity for extensive reforms. They would soon be solicited by candidates for votes and influence. Before pledging themselves he strongly advised medical men to ask candidates that in the event of their being returned they would promise to remember the onerous obligations of the profession, their miserably insufficient payment, the total absence of any approach to uniformity even in the same unions, the risks they ran of contracting mortal disease, and the various forms of illness that might affect them and their families, and to support any measure that might be brought forward with the view of doing them justice. It was very desirable that there should be a central board consisting of responsible members, not dummies —men well-known to the public, and who should consult upon all important questions as they arose, and establish uniformity in all suitable matters. No public department was in such continued bad odour with the public as the Poor-law Board, and this, he believed, was due to its unsatisfactory and unrepresentative character. One thing was very certain, it was absolutely essential that a larger medical element should be introduced into the discussions of the central body. Up to a very recent period there was no medical staff at all, and this arose because the new poor law of 1834 started with the assumption that there were no sick at all; and he remembered that at the time the bill was passed it was prophesied that at no distant date there would be no poor at all. As regarded the supply of medicine as part of the contract of the medical officers, it was derogatory to the character of an educated and liberal profession that the medical officers should be called upon to supply the medicines. In all large towns, and in all possible places, drugs and appliances should be found by the guardians. There might be difficulties in certain localities where the population was thin and widely scattered, but this should prove the exception to the rule. Permanence of appointment he considered to be absolutely requisite if Poor-law medical officers were faithfully and honestly to perform their duty. Without it the medical officer's position was unbearable, and there was no security for the proper treatment of the sick poor. No Poor-law medical officer should be removed without grave reasons for it, and after open public inquiry into his alleged shortcomings. In conclusion, he trusted that they would be united. and that they would show to their opponents that the supposed bane of the profession—intestinal division—would not operate to their disadvantage on this occasion.

Dr. Rogers said that the question was, how could the 1,250,000 persons who annually became the patients of Poor-law medical officers be best dealt with? Should their attendants be provided with proper means to secure a more ready restoration to health, or was the present faulty system to be perpetuated, which perpetrated grievous wrong-doing, not alone on the poor, who were the first sufferers, but also on the good and conscientious of their own class, who faithfully fulfilled their obligations. There was now a very wide-spread opinion that what was popularly known as the "Poor-law Board" was not a distinctive corporate entity, but a mythical body. There was certainly a president and a parliamentary secretary who were known, but generally it was for a very brief period only. Now it was currently believed that because there was a president, a parliamentary secretary, and a "board," that, therefore, there was a deliberative body that met and consulted upon the various questions that constantly came up from the provinces for settlement; but, having had leisure for investigating this subject, he was in a position to assert positively that no such board existed. He would ask who was the board when Lord Devon was away for weeks in the south of France during the terrible distress in the East of London last winter? He very much wished that some independent member would move for the production of the minutes of the "board" meetings—who attended and how often, and generally that they might learn something as to the mode in which the business of an office costing some £60,000 a-year was conducted. If his information was correct, the contradictory policy of the board could be understood, and it could be explained why decisions arrived at at one time should be reversed at another. With regard to the inspectoral system, many of the inspectors were by previous education and pursuits, utterly unfit to carry out the duties for which they were appointed. That was now officially admitted, for the Poor-law Board had recently, by a general order, directed that the workhouse surgeons should do these gentlemen's duty for them. He would ask that there should be a distinct medical department of the Poor-law Board, to which all matters relating to the sick and medical and hygienic arrangements should be referred. Seeing that sickness amongst the poor was so enormous, and their attendants were between 3000 and 4000, this was not an unreasonable request. As an illustration of the glaring inequality of salaries, he instanced the workhouse of St. Marylebone, with its 1700 inmates, where the medical service cost £780 annually, and the workhouse of St. Pancras, with its 2300 inmates, where the salaries amounted to £400 only; and yet both these arrangements had been sanctioned by the Poor-law Board, though they knew that the money was paid from a common fund equally levied on the whole metropolis.

Correspondence.

THE DISTINCTION OF GENERAL PRACTITIONERS, SURGEONS, AND PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the course of my medical career I have often had discussions with my fraternity regarding the above questions, and how the public can distinguish which is which when required on an emergency. It is acknowledged there is a difficulty about it, and, though I do not consider one man a wit less respectable than another, I think the subject ought to be made clear, and many medical men agree with my suggestions, as follows:—

A professional man in general practice should have engraven on his plate, below his name, whatever diploma he may hold, the words "general practitioner;" a pure surgeon, that of surgeon; and a pure physician, that of physician. The public would easily discern the particular class of practice in each case, and the fees customary to be paid, according to ancient custom. Another suggestion I would make is, the professional dress. All black should be adopted, similar to the clergy, who have no further claim to it, solely except habit; but that the general practitioner should wear a black neck-tie; the *operating*-surgeon all red, and the physician all white, with cambric edge; the neck-cloth to be made either of cambric or satin. Lastly, what is the correct court dress, I am asked? as I see several of the profession at court occasionally, but no two alike. The *correct* one for a physician is black velvet; for a surgeon I leave you to define that question, I know not.—I am, sir, yours obediently,

A Member of the Profession.

London, June 18, 1868.

TREATMENT OF THE APPARENTLY DROWNED.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I beg to transmit to you a paper of queries just issued by the National Life-boat Institution regarding the treatment adopted in cases of apparently drowned persons.

We are of opinion that the cause of science would be much benefited if answers to these queries were accurately and promptly reported to this Institution by medical men and others; and, in order to elicit this valuable information, we calculate on your kind co-operation by conceding to this Institution the favour of publishing the queries in the columns of

The Medical Press and Circular.—I am, sir, yours faithfully,
Richard Lewis, Secretary.

Royal National Life-boat Institution,
John-street, Adelphi, June 24, 1868.

"As the cause of science would be greatly benefited if the result of the treatment in cases of apparently drowned persons, were reported, it is requested that answers to the following questions on the subject may be immediately forwarded to the Royal National Life-boat Institution :—

"*Queries.*—1. Date and place of occurrence? 2. Sex, name, and age of person? 3. Length of time immersed? 4. Time from rescue to first sign of life? 5. Time from rescue to recovery? 6. State of the weather, if warm or cold? 7. State of the water? 8. What mode of treatment adopted, whether the rules of the National Life-boat Institution or those of others—if the former, whether the "Marshall Hall" system or the "Silvester" was adopted, or a combination of both? 9. If treatment successful or not? 10. Length of time persevered with? 11. How long were the efforts to restore respiration continued? 12. Was much fluid discharged from the mouth, and at what intervals? 13. Was a medical man in attendance? 14. Remarks, if any?"

LIEBIG'S FOOD FOR INFANTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Allow me to thank you for the article in your valuable journal of June 10, and your correspondent "M. A. B.," for drawing the attention of your readers in the following week, to the necessity of an inquiry into the respective value of infants food in general, by one of the Medical Societies. As manufacturer of the food in question, and having such perfect confidence in the result of the most rigid tests it can be subjected to, nothing will give me greater pleasure than the proposal of your correspondent. At the same time, I hope that similar tests may be applied not alone to Liebig's preparation, but to all other kinds of farinaceous food, with or without Liebig's name. This, indeed, would be a great boon to the profession and to society, for at present there exists much confusion and doubt upon this important subject.

I agree with "M. A. B." that it would be well for the medical profession to suspend judgment upon food which is not compatible with physiology, and in that respect I venture to assert that those kinds which, freed from husks, show the most complete reduction of starch into dextrine and grape sugar are comparatively the best. In the meantime, that the children may not starve, I can supply sceptics with an "authoritative verdict" respecting Liebig's Food as follows :—

"We have been requested to express our opinion on a project for supplying to the infants of poor persons, either gratuitously or at a reduced charge, the preparation of milk introduced by Baron Von Liebig. We have to state that every facility that is given for the purchase and distribution of so good a food as this, will, in our judgment, be instrumental in reducing the intolerable amount of sickness and mortality among infants that we know to exist at present; and we are satisfied that hospital and dispensary work will become more hopeful from the time that we are enabled to assist poor infants with appropriate food :—

(signed)

Edwin Lankester, M.D.
Thomas Hillier, M.D.
C. H. F. Routh, M.D.
George Buchanan, M.D.
John Charles Steele, M.D.
R. Druitt, M.D.
J. Braxton Hicks, M.D.
J. Cooper Foster.
Henry Gervis, M.D.
Herman Weber, M.D.
W. R. Rogers, M.D.
E. Symes Thompson, M.D.
John Westmacott, M.D.
F. Barozzi de Vignole, M.D.
Graily Hewitt, M.D.
F. Edmund Anstie, M.D.
Henry Smith, Asst.-Surg.
B. Curgenven, M.R.C.S."

A verdict pronounced by a society of such talented men, surely ought to be an "authoritative one" in the eyes of the profession, as it is in that of your obedient servant,

16, Tichborne-street, London, W. G. Mellin.

MEDICAL WITNESSES' FEES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—An answer to under-mentioned case in your next publication will greatly oblige,—Yours, &c.,
R. Brown M'Clelland.

Banbridge, June 26, 1868.

A station-master on the Dublin and Belfast Junction Railway was found dead with a pistol wound in the middle of the frontal bone. To see the exact character of the wound it was necessary to make an incision and dissect back the occipito frontalis muscle, and prove that the bullet entered the brain, at an inquest held on the body by two Magistrates.

Query.—Does this constitute a post-mortem under the Coroner's Act, and entitle the medical witness to a fee of £2, 2s. or not.

P.S.—I ask this, as one of the Magistrates has refused giving his name for any amount beyond one guinea.
R. B. M'C.

[Our correspondent is clearly entitled to £2, 2s., the fee for post-mortem examination, without which it would have been impossible to swear to the fact that the bullet had entered the brain and caused death.]

THE TURKISH BATH IN ACUTE BRONCHITIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As the following cases may interest your readers, I beg the favour of their insertion in your valuable journal:—

I was sent for the other night at about 12 o'clock to see the child of a poor woman, said to be dying of suffocation of the chest. On reaching the house, or rather cabin, I found a fine little boy, aged three and a-half years, almost suffocating from an attack of acute bronchitis. The face was nearly livid and much congested; skin hot and dry; pulse rapid; and the wheezing so hard and loud that I could hear it distinctly before I had entered the house. I at once ordered it a full warm bath for 15 minutes, to be followed by a linseed meal poultice over the chest and back, the limbs to be wrapped up in flannel wrung out of hot water, and covered with a dry blanket. In the morning the child was certainly better, and had perspired very freely in the night, but still the symptoms were very severe and urgent. I at once ordered it to be taken to the Turkish Bath, on its return from which the mother reported to me that it was wonderfully better, that the bath had acted like a charm, and after it had been ten minutes in it perspiration set in freely, and the wheezing seemed to have nearly entirely disappeared. I ordered another Turkish bath to be administered in the evening, and the following morning the mother reported to me the child was all but well, and keeping it quiet in bed was utterly impossible; two baths were again administered the following day, and the next the child was perfectly well, and breathing quite natural.

The second case I would mention, is that of an infant of my own which, in December last, at the age of eighteen days, contracted an acute attack of bronchitis through carelessness of the nurse. I found it almost moribund. I had it well wrapped up and carried at once into the Turkish Bath, where its symptoms in a few minutes became greatly mitigated, and at the end of a quarter of an hour a papular eruption made its appearance over the chest and back, greatly relieving the distress of breathing. After the bath, I had a compress of cotton-wadding covered with oil-silk applied over the chest and back, ordered a Turkish bath to be given the next and following day, when the child became quite convalescent, and rapidly recovering. The paroxysms of dyspnœa in this case were very severe, and several times the nurse sent for me to say the child was dying, and that nothing but squills and tartar emetic could save it.

Case 3.—W. G., aged 52, was attacked with pleurisy and inflammation of the lungs. I found him in great pain with great difficulty of breathing, rapid pulse, hot skin, foul tongue, hacking cough, and the characteristic "prunejuice" expectoration. There was much pain in breathing on the left side, and the stethescope gave unmistakable signs of attrition between the pleural surfaces. As it was inconvenient to have the patient wet packed, I ordered a hot stupe to be applied over the chest for twenty minutes, followed by a linseed meal poultice for four hours, after which a wet chest compress was to be applied, refreshing it every two or three hours when very hot or dry. A wet stomach compress was also ordered, and a tepid wash-down at 92° morning and evening. Diet to consist of oranges or stewed apples, and cold water. Suffice it to say that the case made steady and rapid progress to recovery, and in seven or eight days he was up and about his business.

I need not say that in none of the above cases was a particle of medicine or stimulants administered in any shape or form, nor was any drink allowed but milk or cold water, alone or mixed. In the last case, when the appetite improved, gruel or stirabout, with potatoes and cabbage, or other vegetables for dinner, alone were allowed.—Yours faithfully,
R. Griffith, Ch. M.

DR. PROSSER JAMES' PLAN OF REFORMING THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It gives me great pleasure to see that Dr. Prosser James, in his admirable address to the enlightened constituents of the Edinburgh and St. Andrews Universities, expresses himself as in favour of the granting of one State degree in medicine in various parts of the kingdom, by means of *ambulatory examiners*. I am glad to say that in a recent conversation with Dr. Sharpey, that illustrious gentleman also expressed to the writer an opinion favourable to such a change being made. As to the machinery of examination, there seems to me to be but little necessity in looking about for a fresh staff of examiners when we have such an admirable body of men already in combination in our Medical Council.

It appears to me that these gentlemen might easily obtain a charter from Government enabling them to grant a degree for a small sum—say £10—obligatory, as Dr. Prosser James says, on all before any other degrees were taken, but after which any other fancy degree might be added, and which degree (which, I hold, ought to be called Doctor of Medicine) should alone admit to all public appointments, whether in the army, navy, or poor-law services.—I remain, sir, yours obediently,

CHARLES R. DRYSDALE, M.D.

99, Southampton-row, W.C., London,
July, 1868.

GENERAL MEDICAL COUNCIL.

THE Council, while these pages are being printed, are engaged on the discussion of the representation of the Medical Practitioner. The programme for yesterday (Tuesday) contained a notice of a motion by Dr. Andrew Wood:—

"That the Medical Council take into consideration its present constitution, with the view of determining whether it be not advisable that it should be placed on a more popular basis, by the addition of a certain proportion of members to be chosen directly by the suffrages of Registered Practitioners."

This proposition will probably lead to a prolonged debate, and it is therefore unlikely that Mr. Paget's motion—

"That in future every person whose name shall be entered for the first time on the *Medical Register* shall be entitled to receive, on application, a copy of the *Register* for the year in which his name has been entered"—

will come on.

The following communications are also before the Council for consideration:—

6. Communication from the Royal College of Surgeons of England, relative to some of the educational recommendations of the Medical Council.

7. Resolution passed by the King and Queen's College of Physicians in Ireland, relative to the age at which candidates for its licence may be admitted to examination.

9. Application from Dr. Frederick Milford to be registered as M.D. (by examination) Heidelberg, 27th June, 1856.

10. Communications from the Medical Teachers' Association respecting the registration of students.

11. Letter from Dr. James Mason, relative to the Medical Acts Amendment Bill.

12. Letter from Dr. Edwards Crisp, relative to the adjudication of the Carmichael Prize.

13. Memorial from the North of Scotland Medical Association, relative to the position of Parochial Medical Officers.

Medical News.

UNIVERSITY OF CAMBRIDGE.—Scholarships at Sydney Sussex College. There will be an Examination at this College, on Wednesday, October 7, 1868, open to all students who have not begun to reside in the University, when (provided fit Candidates present themselves) the following Scholarships will be filled up:—two for Classics only, £40; two for Mathematics only, £40; two for Natural Science, Heat, Electricity, Chemistry, Geology, Anatomy, or Mathematics, £40; one or more Johnson Exhibitions, £32, per annum each; Two Scholarships may be held by the same person, and each will be tenable for three years at least, or until promotion to another of greater value. *N.B.*—All Candidates will be expected to show a fair knowledge of the *set* subjects in Classics, and also of Arithmetic, the early part of Algebra, and first three Books of Euclid. Books recommended by the Examiners for the Natural Science Scholarships:—Heat and Electricity, Ganot's Physics; Chemistry, Fownes, Church and Northcote's Chemical Analysis; Geology, Lyell's Principles and Manual; Anatomy (Human Osteology and General Anatomy), Gray's Anatomy, and Holden on the Bones. The names of Candidates must be entered on the College boards on or before October 1st. Any further information may be obtained of the Tutor (the Rev. J. C. Williams Ellis). Candidates must present themselves in the College Hall, on Wednesday morning, October 7th, 1868, at nine o'clock.

LONDON MEDICAL BENEVOLENT FUND.—Election of Annuitants.—At a special meeting of Committee two vacant annuities of £20 were filled up as follows:—No. 66. A widow, aged 67, Edinburgh, maintained herself for many years; now suffers from rheumatism and dropsy; on the list of candidates since 1862. No. 67. A widow, aged 70, Sussex, has passed through many misfortunes, suffers greatly from rheumatism, recommended by several eminent members of the Profession; on the list since 1866. The fund has already distributed in the course of the year, in addition to the annuities, £420 among fifty cases of extreme distress.

THE HEALTH OF LONDON.—It appears from the return issued by authority of the Registrar-General, that in the week ending on Saturday, 4546 births and 2754 deaths were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 22 per 1000 persons living. The annual rate of mortality last week was 20 per 1000 in London, 21 in Edinburgh, and 17 in Dublin; 26 in Bristol, 21 in Birmingham, 26 in Liverpool, 80 in Manchester, 23 in Salford, 27 in Sheffield, 20 in Bradford, 22 in Leeds, 16 in Hull, 24 in Newcastle-upon-Tyne, and 28 in Glasgow. In London the births of 1024 boys and 1001 girls, in all 2025 children, were registered in the week. In the corresponding weeks of ten years (1858-67) the average number, corrected for increase of population, is 2054. The deaths registered in London during the week were 1228. It was the twenty-fifth week of the year; and the average number of deaths for that week is, with a correction for increase of population, 1250. The deaths in the present return are less by 22 than the estimated number. The annual rate of mortality was 21 per 1000 in West Londen, 20 in North London, 21 in Central London, 21 in East London, and 20 in South London. The deaths from zymotic diseases were 328, the corrected average number being 335. Five deaths from small-pox, 59 from measles, 32 from scarlatina, 2 from diphtheria, 58 from whooping-cough, 35 from fever, 66 from diarrhœa, and 8 from choleraic diarrhœa were registered. The prevailing high temperature has caused an increase in the mortality from diarrhœa, and has also occasioned some deaths from choleraic diarrhœa. It is of great importance that the utmost vigilance should be exercised by inspectors of nuisances at the present time. The application of disinfectants to drains, and an abundant supply of pure water to every house, are essential. It would be false economy to imitate the Whitechapel board, which has recently reduced its staff of inspectors of nuisances. The deaths from fever were at the annual rate on 10,000 living of 4 in West London, 4 in North London, 6 in Central London, 13 in East London, and 3 in South London. In calculating these results the deaths in the London Fever Hospital have been referred to the districts from which the patients were brought. The deaths of 7 infants and 1 adult from syphilis, of 6 persons from drowning, of 9 infants from suffocation, of 4 persons who committed suicide, and of 6 persons who were killed by horses or vehicles in the streets, were registered. A builder aged 65 years died on 14th June, at 82, Howland-street, St. Pancras, from "coup de soleil, 8 days, effusion, 2 days."

MORTALITY BY ENTHETIC DISEASE.—In the ten years 1857-66 no less than 12,786 lives have been destroyed in England and Wales by enthetic disease (syphilis) alone. The number of deaths registered in each of the ten years was 957, 1006, 1089, 1067, 1177, 1245, 1386, 1550, 1647, and 1662. Allowing for increase of population the results show that the mortality by this disease is steadily increasing; thus, to 1,000,000 persons living in each of the years 1857-66 the proportional number of deaths was 50, 52, 56, 54, 59, 62, 68, 75, 79, and 79 respectively. The results published by the Registrar-General show the lamentable amount of suffering and death which this disease entails upon infant life. Out of 13,914 deaths from enthetic disease registered in England and Wales in the 12 years 1854-65, no less than 9512, or 69 per cent., were those of infants under one year of age; in 1854, out of 964 deaths, 577, or 60 per cent., were those of infants under one year of age; and in 1865, out of 1647 deaths, 1155, or 70 per cent., were those of infants who had not completed their first year of life. In London, in the 12 years 1854-65 3370 deaths were registered from enthetic disease; in 1854 the deaths numbered 206; in 1865 they were 392. Of the 3370 deaths the large number of 2587, or 77 per cent., were those of infants under one year of age. In 1854, the proportion of deaths of infants to total deaths was 43 per cent., in 1865 it was 76 per cent. The deaths registered from enthetic disease represent only a small proportion of the cases, and the syphiline sets up actions which affect various organs, and gives rise to diseases referred to other causes of death.

Association for Promoting the Extension of the Contagious Diseases Act.—A general meeting of the members of this association was held on Friday, at St. James's Hall; Sir Thomas Watson, Bart., in the chair. A report going at length into the objects of the association, and giving statistical evidence of the great prevalence of the disease which the association sought to grapple with, was presented to the members. The Chairman, in the course of his remarks, stated that such were the ravages of this disease that in one of the largest hospitals of the metropolis, amongst the surgical out-patients half were found to be suffering from it, and in the children's hospital there were 174 children treated for this alone. The Act of 1866 was already in operation amongst soldiers and sailors, and it was the object of the society to extend its benefits to the civil population, but denied that any member of the society, in pressing this matter, had any idea of licensing prostitution. The meeting was further addressed by several members of the profession and others, and resolutions were passed adopting the report, authorizing the carrying out of the objects of the association, expressing an opinion that the "Contagious Diseases Act" should be extended to the civil population of the country, and that petitions upon the subject should be presented to both Houses of Parliament.

At a meeting of the Metropolitan Board of Works on Friday last, some magnificent samples of wheat, oats, &c., were shown, as results of the utilization of London sewage, on land hitherto comparatively barren.

It has been determined to proceed with the new Fever and Small-pox Hospital in the neighbourhood of Brixton, notwithstanding the strenuous opposition of the inhabitants; the Poor-law Board holding out no hopes that they can interfere.

◆

NOTICES TO CORRESPONDENTS.

Proofs reaching authors in England on or before Friday morning are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper only.

Sanitas.—Owing to unusual pressure on our space, your communication is unavoidably postponed.

Dr. C. Drysdale.—The One Portal System—see previous reply.

"FLUID EXTRACT BELLADONNA."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In reply to your correspondent Mr. Johnston, there is no accredited preparation called *fluid extract of belladonna*. Other fluid extracts in the Pharmacopœia are made simply by stopping the process whilst in a state of fluidity, such as sarsaparilla. I therefore apprehend that extract of belladonna, which itself is a *soft solid*, if made semi-fluid by water, would answer the purpose.—Yours, &c.,

A Member of the Pharmaceutical Society.

MOLLER'S COD-LIVER OIL.

The Norwegian Medical Society having received an application relative to the medicinal use of pale cod-liver oil prepared by Peter Möller's process, the subject was duly discussed at the meeting of the society held on 15th January last. Professors Chr. Boeck, Heiberg, Voss, Zochmann, the President of the Society, and several other members, took part in the discussion. From the information supplied and authenticated on that occasion, it may be laid down as a fully-substantiated fact that the physicians to the hospital and the profession generally in this city rarely, if ever, prescribe the brown oils, and when they do so, from economical reasons alone, having a decided preference for the pale oil obtained by Mr. Peter Möller's mode of preparation, the latter having been proved by experience to be equally powerful in its therapeutic action, far less nauseous, and much easier of digestion. Several officially appointed practitioners who attended the meeting gave evidence to the effect that this variety of pale oil, though more expensive, is administered even to pauper patients, on account of its singularly beneficial and salutary properties.

Otto Zund, President.
A. Holst, Secretary.

Christiania, January 30th, 1868.

APPOINTMENT.

Hayward, Sidney, M.D., has been appointed a Physician for out-patients to the Samaritan Free Hospital for Women and Children.

DEATH.

Burke—At Scariff, June 20, Thomas Burke, M.D., of Killaloe.

Advertisements.

NOTICE TO ADVERTISERS.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0 3s. 6d.
Per line afterwards.................	0 0s. 6d.
One-quarter page....................	1 0s. 0d.
Half ,, ...	1 15s. 0d.
One ,, ...	3 0s. 0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the Office, on Saturday, by Three o'Clock.

EASY CHAIRS, COUCHES, AND SOFAS,
THE BEST MADE.
300 different shapes constantly on view for selection and immediate delivery. Easy Chairs made to any shape on approval.
FILMER AND SON,
UPHOLSTERERS,
31 & 32, Berners-street, Oxford-street, London, W.
Factory—34 & 35, Charles-street.
An Illustrated Catalogue post free.

WEAKNESS.—The finest TONIC is WATERS' QUININE WINE, unrivalled as a stomachic stimulant. Sold by grocers, oilmen, confectioners, &c., at 30s. per dozen. WATERS & WILLIAMS, the Original Makers, 2, Martin's-lane, Cannon-street, London.

THE PROGRESS OF SANITARY IMPROVEMENTS IN EXISTING HOSPITALS.

By F. OPPERT, M.D.

(Read before the Medical Society of London.)

Every subject connected with public hygiene finds a deserved attention in this country, and great care is at present bestowed on all measures for the prevention and treatment of diseases.

Hospitals are capable of being improved in many ways, and it is useful to take notice of every recent improvement introduced with advantage, and to direct public attention constantly to these important matters.

HOSPITALS NOT CAPABLE OF IMPROVEMENT.

There are of course some hospitals in existence which cannot be improved at all, their construction being radically faulty, and they are better pulled down to give place to others, than wasting money on their improvement. The old Hôtel Dieu in Paris belongs to this order, and though still in use, will shortly come down. The new building, which I saw in course of construction at a recent visit, stands close to the old one, and is being built on the pavilion plan. The Circular Asylum in Vienna, the Lying-in Hospital in St. Petersburg, some military hospitals in Prussia, the old Fever Hospital in Glasgow, and other institutions, have been found utterly unfit for improvement, and are now replaced by others. In many establishments the process of improvement goes on without remittance. Many hospitals in London, Paris, Munich, Berlin, and Vienna are already materially improved, others will be gradually ameliorated.

PREVENTION OF OVERCROWDING.

There is one mode of improving the healthiness of even a very defective building, viz.: by diminishing the number of inmates, and by occasionally emptying the wards. It is a pity that, in many instances, this is not done before hospital diseases, such as erysipelas, pyæmia, fever, etc., make their appearance. As regards London hospitals, the new workhouse infirmaries and the foundation of new convalescent hospitals are likely to diminish the press for admission and overcrowding. It has been found in Vienna, that the healthiness of the General Hospital was improved by the foundation of the new hospitals, Wieden and Rudolphstiftung, which receive a portion of the sick population.

A hospital should never be too full. But I actually found last year, additional beds placed in the wards in excess of the number originally intended, and I also saw two patients placed in one bed in an infirmary. I should consider it far more expedient to construct temporary sheds or tents in the garden or yard than to overcrowd the wards.

CLASSIFICATION OF PATIENTS.

Another means of improving the arrangements and furthering the cure of disease is by proper classification and distribution of the patients in the building. It is well-known that the pavilion plan offers great facilities in this respect, but also in corridor hospitals much more can be done than is done at present.

First, as to separation of sexes, we find sometimes men's and women's wards adjoining on the same floor as in the Manchester Infirmary, the proposed cottage hospitals offer the same objection; at other times both sexes use the same yard or garden for exercise, or they sit together in the convalescent or waiting-rooms. This might easily be better arranged. In many Paris hospitals there are separate gardens for men and women, for instance in the Charité; in many German hospitals the men occupy one side of the building and court-yard, which by-the-bye may be tastefully laid out with shrubs, and females the opposite ones.

Next, as to age, children are often found in the wards of adults (St. Bartholomew's Hospital). But this is undesirable, as children ought to have specially trained nurses, and they require special utensils. It is also for the sake of decency necessary that they should be separated. Therefore special wards or blocks and special play-grounds should be given to them, if they must be admitted into the establishment.

Thirdly, medical and surgical cases should not be in the same wards as in the Royal Free Hospital, though no evil consequences, I was told, are observed there. It has, however, been noticed in military hospitals that where fever and surgical cases were close together, the wounds often became sloughing. In some cities surgical cases are exclusively admitted into surgical hospitals: in Rome two buildings of this description exist. It is well-known that the London general, hospitals admit surgical cases in excess to medical ones, and place more beds at their disposal, and that they contain special accident wards.

It has scarcely to be mentioned that women in their confinement must be kept as separate as possible from fever as well as surgical cases.

Again, certain medical cases should be separate from others. In hospitals which serve for clinical instruction, we generally find the more important cases removed to special wards, which are arranged with special care, and the lighter cases are in other rooms. This is better than a clinical teacher having his cases distributed through the wards. We often find a female department, especially one for cancer (Middlesex Hospital, Berlin Charitê, and some Paris hospitals), and this seems a satisfactory arrangement. It is rare that patients with lung diseases are congregated in the same wards (as in Traube's wards in Berlin), but this is convenient for clinical instruction in auscultation. Contagious diseases, such as small-pox, measles, scarlatina, &c., should always be treated in separate rooms. Also, noisy patients should have separate accommodation. A more doubtful question is whether patients attacked with typhoid, or typhus, fever should be excluded from the medical wards of a general hospital or not. To discuss this point alone might occupy a whole evening. State hospitals are conducted on different principles, in this respect, to private ones, the former being liberal in their admission, the others act on restricted principles. We find, however, in this country hospitals supported by voluntary contributions, which admit fever patients into the general wards, for instance Leicester, and this without detriment to the others. In Germany, where typhoid fever, the less contagious form of fever, is more common than typhus, fever patients are constantly with the others. It seems to me that the contagiosity of the fever varies in different countries and places, and at certain times, and that the question how to accommodate fever patients must often be decided on local grounds.

As for surgical cases, they should be on the lower floors, accidents especially; eye cases should be separate, as nothing is more dangerous to the results of eye-operations than a traumatic atmosphere. Special eye wards are generally found in Continental hospitals—Berlin, Vienna, &c., but it is only lately that attention has been paid to this arrangement in this country. So I read lately that certain London hospitals have adopted this plan, and it can easily be instituted in many country hospitals. A dark room, for ophthalmoscopic researches, has to be added where needed.

Special departments for other patients—viz., ear, laryngoscopic, female cases, may, in many instances, be advisable, not only for the purposes of medical education, but to prevent the starting of too many special hospitals.

Lock wards may be added the more easily to general hospitals, as the syphilitic patients can very well be accommodated in the attics, and new attics can be built for them if necessary.

ACCOMMODATION OF THE OFFICIALS.

The officials should be properly accommodated. It is very rare that any one takes the trouble to visit the servants' rooms. I believe that Continental hospitals are more defective in this respect than those of Great Britain, as it is not rare to find these people living underground in the former establishments. If I remember rightly, something of this sort may be found in Hamburg and Berlin. In some French hospitals I found too many beds for night nurses (vieilleuses) placed in one room, and so it is in some English hospitals. Recently the servants of St. Mary's Hospital have received better accommodation, and the nurses of University College Hospital are about to enjoy more spacious sleeping-rooms.

VENTILATION.

I come now to a most important question which never should be lost sight of by hospital authorities, this is how to improve the ventilation. The cubic space is easily increased by diminishing the number of bedsteads, but to improve the circulation of air in the wards is more difficult. You have often to remove partition-walls, form apertures in the walls and ceilings, place louvres over the doors, put in hopper-mouthed window panes, or institute ventilating fires, &c. There are some managers of hospitals on the Continent, and I had the honour to confer with them on the subject, who make light of such improvements as I just mentioned; they aver that it is quite sufficient to open the windows occasionally, and pay the greatest attention to cleanliness by removing everything immediately which might cause bad smells, keeping the bed-linen in the best state, &c. But in this country we think different, and much has been done in this direction. The Royal Manchester Infirmary, a corridor hospital for about 250 patients, which is cut up into a great number of small wards, may serve as an example. Fine end wards have been formed with windows on more than one side by taking down partition-walls, and other wards have had square apertures placed opposite the windows, and louvres have been formed over the doors. The old infirmary of Leeds has been improved similarly, even some ceilings which were too low have been raised.

The new (Hunt's) block in Guy's Hospital has been improved by cutting apertures in the wall for the admission of air. The Charité Hospital in Paris has been greatly changed. New wings built on improved principles are added, some of the old wards are much improved. For instance, the ward St. Charles, which contains twenty-five beds, had a low arched ceiling, as usual in hospitals which were formerly convents. This ceiling is now pierced in four places, and skylights placed there to admit light and air. This ward is warmed by calorifères, but a convalescent-room, which has been cut off from it by a glass partition, contains a chimney-place with marble slab.

Ventilation can be much improved by paying attention to the construction of windows. They are generally sash-windows in this country. I may mention that the Lock Hospital in Harrow-road has some French croisées, and in the Kensington Workhouse Infirmary I found the same. I have not seen sash-windows in Germany and Italy, I observed a few in the Incurables Femmes in Paris, an old building which is to be vacated. Windows inclining inwards, revolving on their lower border, have been introduced with advantage in many English, French, and German hospitals. They are sometimes fixed by small boards against which they incline when open, at other times by ropes and pulleys. They are found in the hospital Rudolphstiftung in Vienna, and will be in the new Hôtel Dieu. The windows of the New Leeds Infirmary are partly on the French croisée principle. In some hospitals (Whitworth, Arbroath, Manchester), perforated zinc plates are placed before the upper sash. When this is lowered the air percolates through the perforations. I wonder why we do not more often find similar arrangements, as in railway carriages, for instance. I would place double zinc plates the whole width of the upper part of a window, say five inches high, sliding on each other to regulate the draught. I mention in another place that in the justly praised Chorlton Union Hospital, the draught from the ventilating apertures is too strong, this leads to plastering up the apertures as in Leicester.

Much more difficult than to admit fresh air it is to institute the means for extracting vitiated air in an old building. There are, however, instances where chimney shafts have been formed with this object.

WARMING.

The means for warming can be improved in different ways. The Paris administration has lately introduced open fire-grates in some hospitals, the Charité, les Cliniques, Hospital Cochin, St. Louis. In the latter hospitals the chimneys have gone through singular transformations. In the middle age the large chimney-places of the square wards were heated with wood-blocks, later they were replaced by calorifères and blocked up, but I was surprised at my last visit to Paris to find them again prepared for use. If the warmth is deficient we can place Gurney's stoves into the wards (German hospital), but I should not think it so difficult to form water-pipes into coils to be heated from the basement. Quite recently objections have been raised against cast-iron stoves by Dr. Carret. The artificial means for warming and ventilation have not always answered, and open fire-grates had to be built in their stead. Smoky chimneys or stoves must not, of course, be tolerated.

FLOORS.

I have not much to say about the floors, walls, and ceilings of hospitals. In Paris, where some hospitals had stone-floors, these have been replaced by parquet ones, les Cliniques, Charité, St. Louis. In English hospitals, some deal floors are now oiled and lacquered—King's College Hospital, Newcastle. In bath-rooms tiled floors are in their right place (Cambridge, Lock Hospital, Harrow-road). In France, every grocer sells the material which is used to lacquer the floors; walls, and ceilings, which are not coated with cement, want repairing or whitewashing about once a-year.

FURNITURE.

The furniture, which the wards contain, can easily be improved where necessary. The Paris Administration has nearly all other bedsteads replaced by such as are provided with spring-mattresses. They are more easily kept clean and free from vermin, the quantity of horse-hair contained in the mattress is only 18 kilogrammes, or 40 lbs. I saw some very useful hospital furniture in the Paris Exhibition —night-tables, contrivances to raise the patient, &c. All the London hospitals should gradually replace their beds by better ones.

WATER-CLOSETS AND LAVATORIES.

That the salubrity of a hospital is endangered by badly placed water-closets or latrines and drains is well-known, and it is therefore desirable where they are faulty to remove the nuisance. These things are better arranged in England than elsewhere. I have, however, pointed out in another place that we are not altogether free from blame. At the Oxford Ratcliffe Infirmary a nurse's-room is, or was till recently, squeezed between two water-closets. The Paris Administration is gradually replacing the latrines by water-closets. The new ones of Lariboisière are quite on a level with English ones. La Charité, les Cliniques, the new part of Cochin, Beaujon, la Salpêtrière, are provided with new water-closets. It will not be long before we will have to search diligently for the ancient latrines which everyone who sees them for the first time contemplates with amazement. Low seats of stone with a small round opening, not fit to sit but to stand upon, as constructed more than 100 years ago, are still visible at the Charité and Salpêtrière. Earth closets I did not see in hospitals, but I noticed them in the Exhibition. They seem to me the next best thing to water-closets, especially in hot climates. Lavabos are not difficult to place where they do not exist. In France, they have generally marble-slabs, whereas the English are content with slate.

Water-closets and the place where the lavatories are, are rarely warmed, it should become in future the object of architects not to overlook this. In Guildford Hospital, Herbert, New Leeds Infirmary, and the Brompton Hospital, the means for warming are found. In consumption hospitals especially they should not be overlooked. The best means are small chimneys or warm air, which has passed over hot pipes.

OPERATING-ROOMS AND LECTURE-ROOMS.

They are not always what they should be. Where they are not light enough, windows may be formed at the proper place. Some hospitals have had new ones added lately at a considerable outlay—viz., Guy's Hospital. The most ancient amphitheatre I saw recently is that of Bouillaud in the Charité Hospital. It is of a round form, the chair in the centre, the seats rising steeply, the light sparingly falling through a round skylight above the chair. 300 students may be seated.

THE POST-MORTEM ROOMS

are badly arranged in many of the old buildings, and might be replaced by separate detached deadhouses, care being taken that the patients cannot see the funerals.

THE BATHS

are capable of much improvement in English hospitals. The more recent establishments are somewhat more satisfactorily arranged, but the older ones contain neither a sufficient number, nor are the baths of the proper material.

Enamelled earthenware I consider the best material for the fixed baths. In Paris, a great many newly instituted baths are of enamelled cast-iron, and they look beautiful, but they are less durable than the former. Zinc-baths are not rare with us or on the Continent; copper-baths are much valued in Germany (Berlin). The finest baths are those of one piece of marble, as exhibited last year in the Italian gallery of the Exhibition, but they are very expensive.

Hot air or Roman or Russian baths are rarely met with in British hospitals. I may mention they are to be found in Cambridge, Colney-hatch, and Herbert Hospitals; they will of course not be missing in the New St. Thomas's Hospital, French physicians are much struck with the deficiency in this respect, great value is attached to them in France. In Germany, the larger establishments (Charité, Rudolphstiftung, and others) usually contain these baths; and so they do in St. Petersburg. Occasionally a voice has been lifted in their favour in England, but as yet with little success. The same must be said of sulphur baths. Almost all hospitals in Paris, where skin diseases are common, have plenty of these. The famous baths of Barèges in the Pyrenées are much valued, and produced artificially in French hospitals. In the same manner the "Mother of Lye" baths are used in Germany. Soda and sea-salt baths find some favour with English Hospital Physicians. A number of other artificial baths used in Paris, as seen from the report of the administration, are almost unknown in London. The atomized baths of Mathieu de la Drôme seem not to find much favour with our French colleagues, as they are only instituted in St. Louis and another hospital.

Appliances for fumigations for the cure of syphilis and skin diseases should be added to the baths in English hospitals. The hydro-therapeutic apparatus are brought to great perfection and used in Paris, but there is some caution necessary regarding their use, especially as respects the Douche. A plan of treating habitual constipation by shower-baths is not much known in England. There is some danger of falling into the error of treating too many diseases hydro-therapeutically where the apparatuses exist.

Portable hot air and vapour-baths may, of course, be easily acquired for an hospital, and I have reason to recommend them. There is some caution necessary to prevent accidents with them. A new appliance, the bidet, which I found in several French Hospitals, may be introduced in English ones. I was pleased to see it in the female lock-hospital.

The warming of bath-rooms is often considered superfluous. As an instance, I refer to the new Alexandra wing of the London Hospital, opened only two years ago. Some of the bath-rooms are partitioned off the ward by an opaque glass partition, and are rather dark, but there is a gas-burner. No means of warming nor for the escape of steam are provided for, so the steam enters the ward. Such arrangements should be ameliorated. An apparatus for warming the linen must not be over-looked

As it seems very difficult, and in some cases not possible, to provide London hospitals with the desirable Russian baths, appliances for fumigation, sulphur baths, &c., I suggest that a central establishment for medicated and other baths be founded; hospitals, infirmaries, and dispensaries to support the institution by becoming subscribers for tickets, the tickets to be distributed on an order from a medical man connected with the hospital. I know cases where patients with skin diseases have not been admitted into the public baths. An institution of the kind supported by the profession and well managed, would be an undertaking which might be taken in hand by a public company with the greatest success, and be an inestimable boon to the poorer classes of the metropolis.

DINING-ROOMS OR HALLS

have found much favour with hospital authorities in this country, and there is no doubt that they often prove a desirable addition to many buildings. They are more necessary where the number of light cases is large, and may therefore not be out of place in many country hospitals where the privileged light cases are often largely admitted to the detriment of the real sufferers from disease. Those patients who cannot leave their bed enjoy a larger cubic space by the others vacating the ward; the attendants are saved a great deal of trouble by serving a greater number at one time; the patients do not get their dishes cold, and dine comfortably together. Therefore, notwithstanding some disadvantages which I know quite well, I consider the addition of dining-rooms an improvement.

PATIENTS' LIBRARIES

can be easily connected with the recreation rooms, and when libraries do not exist, the chaplain of the hospital should make it his business to form them. Such a library, recently founded, I noticed with pleasure at my last visit to the Sheffield Infirmary.

LIFTS

have been lately added to some establishments, for instance, University College Hospital. They serve to carry the dishes from the kitchen to the upper stories, and are very useful. Also,

LINENSHOOTS

can be formed where they do not exist, and it is well-known that earthenware tubes deserve the preference. I need scarcely add that many other improvements are of more importance, and should therefore first be attended to.

DISPENSARY.

The place where the medicines are made up is often too dark, and in that event should be made lighter, or the dispensary removed to another part; for instance the dispensary of the Herbert Hospital is defective in this respect. A small gas-apparatus is very convenient for preparing infusions and decoctions, and might be added, a defective sink and lavatory might be replaced by an improved one. Medicine vessels should be provided with stoppers. The preservation of cod liver oil, especially in large establishments and consumption hospitals, makes some precautions necessary. The principal store is in a cool place in the cellar. A stone barrel with a tap should be kept for it in the dispensary. The objection is raised that such a barrel might be difficult to cleanse, their being only a small opening for filling it, but I think this is not the case. The next best things to be recommended are the glass vessels with double margin. For larger stores a slate tank, under which a current of air passes, is desirable. Poisonous drugs have to be kept always separately; distilled water kept in stone jars.

KITCHEN.

This is a much neglected department in English hospitals. Many kitchens are in the basement, and too low, badly lighted, etc. The ceiling may be carried higher (Sheffield), or the floors lower (Windsor), but it is preferable, where possible, to build a new kitchen. The Berlin Charité Hospital is an instance of this improvement. A large kitchen was built attached to one of the wings of the old hospital a few years ago. Almost all the kitchens of the Paris hospitals are lofty, airy, and have opposite windows with vasistas for ventilation, the smoke flues are carried under the floors which are of stone. For fuel they use coke, formerly coals were used. A central range usually has four fires. Coke wants a little more time before it gets thoroughly heated, but is cheaper than coals. Steam I found employed for cooking, but in one establishment—viz., St. Anne; in Germany they generally cook by steam. Gridirons for chops or steaks with side or down-draught can be instituted where not found. For storing the provisions which are to be consumed, I noticed in Paris, and recommend for imitation, airy meat rooms like the new one in the Salpêtrière, stone floors, marble slabs, or slate, tiled walls, opposite windows, etc., ice in summer. Milk to be kept in enamelled slate tanks with air draught underneath (Brompton). Meat-safes, hot plates, tin boxes for the lifts, and many modern improvements of minor importance may be added.

THE WASH-HOUSE.

The plan of having the washing of several hospitals done at one of them is a good one, and, of course, easily acted upon, where a central administration exists as in Paris. I have found the washing attended to at the smallest institution I visited—viz., at Windsor, an infirmary for twenty patients—and, on the other hand, large hospitals do not undertake it—for instance, the Brompton Hospital. It may not be feasible to act upon the principle of co-operation in London, but there may be country towns more favourable for it.

Only very small institutions should be without a steam-engine, and no large amount of washing should be done without steam-power. It is true that the linen wears longer if only subjected to hand-work, but this is so much more expensive that it cannot be thought of. I am convinced that a great amount of labour and money might be saved in this country by better managing these matters, and adopting some of the continental principles. These matters are too much left to the ingenuity of the female mind, and time and labour is often wasted. I found washing by hand done before the things were put in the machines; in fact most things were washed twice over, which I should think only necessary in a fever hospital. The French way is far more expeditious, as hardly anything is washed twice. It is very singular how the different countries adhere to their own ways, and that, for instance, the *modus operandi* in France should be different from that of Germany, and both differ from the English one.

In all the large French wash-houses—say, of Lariboisière, of the Salpêtrière, or the Incurables Femmes—I was told that the dirty linen, after being wrinsed in cold water, was not washed by hand, but at once thrust into the steam-tubs, where the water was gradually raised to a high temperature. The water, mixed with hot ley, percolates the linen for four hours, after which time it is ready for the washerwoman.

The German procedure, as in the Berlin Charité, and many other establishments, is a little more tedious. The linen is wrinsed in cold water, subjected to the action of hot ley—the temperature being moderate—for twelve hours, removed into the steam-tubs, where it is steamed for three or four hours, washed in hot water, wrinsed, &c.

This system was partly adopted from a French model, and the precepts of Bourgnon de Layre, but replaced in France by that of M. Bouillon. The tubs à arrosage are not exactly a new invention, but they are an improvement on previous apparatuses.

I cannot describe all the washing-wheels and machines, the wringing ones and hydraulic presses; suffice it to say that the French plan deserves a trial in this country, and a good opportunity exists in the new St. Thomas's Hospital.

THE OUT-PATIENTS' DEPARTMENT.

It requires improvement in many English hospitals. Many of them were built without architects paying much attention to the subject, and we find the defects the more striking the more the number of out-patients has increased. The possibility of this department being used for purposes of medical education did not, of course, occur to the builders. The waiting-rooms are almost as a rule defective in the country and in London dispensaries. How often have I seen the patients, male and female, sitting together in the hall, blocking the way to the stairs or consulting-rooms, exposed to draughts, &c.

The consulting-rooms have often insufficient light. The patients should have a separate entrance and exit, in order not to be in each other's way. The rooms should be quiet, and therefore separated by double doors or lobbies, from the waiting-room.

Where the department is used for medical instruction, several consulting and private examination-rooms should be found near the principal entrance. The lecturer must be enabled to detach some of his pupils for examining the patients, and go on lecturing to the others. The names of the patients must, of course, be inscribed in a book kept for the purpose, and case-books for interesting cases be found besides; assistants and famuli, elected according to seniority and merit, should be trained to attend to these matters. The dispensing department should be placed in such a manner that the out-patients pass by it when they leave.

◆

NOTES ON SOME PECULIAR CASES OF SYPHILIS.

By ANGUS M. PORTER, M.D.

(Read before the Ulster Medical Society).

Case 1.—Mr. L., a young, unmarried Scotchman, of fair complexion, and free living habits, contracted the disease in Dublin about ten days before coming for advice. Had never suffered from syphilis previously. Five days after connexion he noticed an inflamed spot on the upper part of his foreskin.

On September 22, 1867 (the date of his first visit), the appearance of the sore was so indefinite, that it was impossible to determine whether it was specific or not; a dry elliptic chafe being the form it assumed. Recommended rest, a mild purgative, and, locally, cold water dressing.

24th.—The dorsal part of the foreskin was considerably inflamed. The sore, on being exposed, presented a suppurating surface. There was no constitutional disturbance nor any enlargement of the neighbouring glands.

26th.—The ulcer was covered by dark sanguineous matter, the edges raised and hard. The prepuce was much swollen, but the system remained perfectly tranquil. The strong nitric acid was carefully applied, and then water dressing.

He did not come back till October 2, when, on examination, the surface of the sore was found clean, the margin, however, remaining high and indurated—there was complete absence of pain or irritation. The healing process did not seem to have commenced as yet. For the first time he appeared depressed, and had a bilious look. The various glands still remained unaffected.

Prescribed one 5 grs. Plummer's pill, to be taken each night for a week, and large doses of decoction of sarsaparilla daily, the topical remedy being altered to blackwash.

Next day he returned much better, the ulcer looking healthy.

He continued to improve till October 9, when he complained of soreness and stiffness in his right groin, for which a spica bandage was employed, and rest recommended. The chancre had begun to heal rapidly, but considerable hardness remained around the edges. Some red oxyde of mercury was dusted freely over it.

16th.—The chancre had disappeared, leaving a fine purplish skin behind it, surrounded by slight induration. The patient still complained of tenderness in the groin. He was continuing to take large quantities of the sarsaparilla decoction.

He now left, promising to return as soon as convenient, which he did on November 5, when he reported himself as completely cured. There was no hardness remaining to indicate the situation of the chancre, and the abortive bubo had quite disappeared. Up to the present he has enjoyed excellent health.

In this gentleman's case, which, from its persistency and difficulty of cure, was undoubtedly one of a specific nature, at least one feature of interest occurred, and that was the presence of induration unsupplemented by any form of secondaries. This hardness, as has been noticed, was not the result of a cicatrix, nor incidental, but evidently characteristic of the form of ulcer which it accompanied, inasmuch as it occurred a considerable time before the healing process commenced, and subsided on the disappearance of the sore.

Case 2.—Mr. A. G., of Belfast, occupied as a clerk, of dark complexion, bilious temperament, regular habits, young, and unmarried.

On October 2, 1867, he first sought advice for three non-indurated, flat, round, ulcers, two of which were situated on the mucous surface of the right side of his foreskin, and one on the left side. A large bubo had formed in the left groin; considerable constitutional disturbance was also present. He stated that he had not had connexion for six weeks, and that it was two since he first noticed the sores.

He had never been the subject of venereal disease prior to this attack. On drawing back the foreskin he experienced intense pain; a good deal of smegma had consequently been allowed to collect, and keep the chancres in a foul condition. After the removal of all the secretions by warm bathing, the strong nitric acid was freely applied, followed by cold water dressing. Pressure, by means of a pad and spica bandage, was put upon the bubo, and perfect rest inculcated.

The following day (Oct. 3) the chancres were looking clean and not so sore, the bubo, however, was causing him considerable inconvenience. He was now recommended to use blackwash as the local remedy, and the following internal medicines :—

℞ Hyd. bichloridi, gr. ii.
Infus gentianæ co., ℥viii. M.
Ft. mist.

Sg. A teaspoonful at each meal, and 20 drops of the tincture of perchloride of iron three times daily. His diet to be plain and nourishing, and his mode of living regular. His bowels being confined, two teaspoonfuls of the liquid extract of senna was prescribed to be taken at bed time.

October 5th.—The aperient had acted freely, which gave him some relief. The chancres were looking better, and not causing much annoyance. The bubo, however, was intensely painful, and the system considerably disturbed.

His next visit was on October 11th, when the chancres did not seem to be doing so well, this it appeared was owing to his own dread of drawing back the foreskin to dress them. Some red precipitate was now applied to each of them.

14th.—The change, which had taken place in the sores was most satisfactory, and the patient now felt less difficulty in applying the dressings himself. The bubo, which had pointed, was freely opened, and a large quantity of thin pus allowed to escape. The general disturbance of the system had greatly abated.

16th.—The chancres were almost healed, but the bubo continued to discharge watery matter, and was still very painful, especially when walking.

19th.—The chancres had quite disappeared, but the affected groin continued to resist all attempts to bring about a healthy condition. The diseased gland was re-opened, and covered with a linseed poultice. A considerable quantity of thin serous matter subsequently drained away.

25th.—The oozing had nearly ceased, so pressure was substituted for the poultice, by means of a sponge pad and close fitting truss. At this time his general health was unimpaired.

November 3rd.—Mr. A. G. left to fill a situation in England, and had apparently quite recovered from the disease for which he was treated. He felt in excellent health, and had ceased to take the prescribed medicines. Scarcely any trace of the bubo remained.

26th.—A letter came from him, stating that the glands of his neck were swollen, and his throat sore. The general tone of his letter indicated despondency.

In reply, the following treatment was recommended—

℞ Pil Plummeri ʒi
Div in pil duodecem

Sg. One 3 times daily, with a wineglassful of decoction of sarsaparilla. Ten grains of chlorate of potass (in water) night and morning; and twelve grains of Dover's powder every second night, also a gargle containing astringents.

December 4th.—There was another communication from Mr. A. G., to say that he was no better. In answer, I advised him to take two teaspoonfuls of cod-liver oil three times daily, and to persevere with the remedies already prescribed.

Subsequently, finding no improvement in his state of health, he went under medical treatment in England.

January 20th, 1868.—He returned to Belfast, having become impatient and discouraged by the obstinacy of his maladies. His face was now covered with pustulæ, while over his trunk and limbs a squamous eruption had become thickly developed; some of the spots were bright red, others purple, and the remainder copper-coloured. His tonsils and the back of his throat were extensively ulcerated. He was greatly dejected in spirits, and suffering from a severe cough which, on examination of the chest, proved bronchitic. His bowels were pretty regular, his tongue clean, skin moist, and pulse normal. Whilst in England, his medicines had been altered, with the exception of the Plummer's pills. He objected to take any more mercury although he had never been salivated, nor otherwise felt the unpleasant effects of this drug. Owing to his pertinacity on this point, I thought I would give the terchloride of gold and sodium a fair trial. Accordingly, he was recommended to take one of Grötzner's pills,* with two teaspoonfuls of cod-liver oil three times daily; and, for the cough, an anodyne pectoral mixture containing the dilute mineral acids and muriate of morphia, together with expectorants. His throat was thoroughly cauterized with nitrate of silver, and a strong astringent gargle prescribed for frequent use.

Feb. 3rd.—He seemed in a somewhat better condition, as regarded his general health. The cough had become easier and less frequent. His appetite had improved, and he rested more comfortably at night.

The pustular rash on his face had increased, especially on the chin and forehead; where any spots had died away, a deep purple stain remained.

8th.—He was almost free of the bronchitis, and in better spirits, though he was somewhat alarmed at seeing a new form of rash present itself—viz., roseola of a very bright colour, principally situated on the chest and arms. The appearance of his face was very disagreeable on account of the confluent nature of the pustules, which in some places were discharging a yellowish matter. He had now taken 57 of the pills, or better than 2 grs. of the terchloride of gold and sodium (which quantity of corrosive sublimate I have seen remove equally severe cutaneous eruptions, and in a shorter time). Not having noticed any marked beneficial effects from this preparation, I deemed it judicious to adopt the following (without consulting my patient on the subject):—

℞ Liq. hydriod hyd. et arsenici, ʒss.
Syr. Simplicis, ℥iss. M.

Sg. A teaspoonful in water with each principal meal. The cod-liver oil being continued.

His hair had commenced to fall out in large quantities, for which symptom Erasmus Wilson's prescriptions were adopted—viz.,

℞ Ung. hydr. nit. ox., ʒi.
Adipis odoratæ, ℥iii.

Sg. To be rubbed well into the roots of the hair at bedtime:—

℞ Ol amygdalæ dulcis, ℥i.
Liq. Ammon. fort., ʒi.
Spts. rosmarinæ, ʒii.
Aq. Mellis, ℥ii. M.

Sg. To be sponged about the roots of the hair each morning.

16th.—A slight improvement was observable in the general condition of the patient, yet the cutaneous eruptions were very perceptible. With the hope of aiding their removal, one part of citrine ointment, in two of simple cerate, was directed to be rubbed on them each night.

March 14th.—The patient's general health had become very good. The skin affections were quickly disappearing, leaving the surface of the body covered with scales and crusts of various shades and sizes. The hair had ceased to fall out.

29th.—A vast improvement had taken place in every feature of the case. No ulceration of the throat remained, though on rising in the mornings a peculiar dryness was felt which a drink of cold water immediately relieved. The medicines were still continued.

April 16th.—No trace of cutaneous disease remained save some slight red marks on the face. The patient's appetite and general health were good, and he appeared in excellent spirits. All medicines were now omitted.

Mr. A. G. paid his last visit on April 20th, on which date every symptom of the disease had vanished.

In this case the plurality of the chancres, the absence of induration, and the late development of the roseolar rash, are points of some interest, as well as the absence of ptyalism during a lengthened course of mercurial treatment. It may be well to remember that cod-liver oil was administered throughout.

(To be continued.)

Hospital Reports.

RICHMOND SURGICAL HOSPITAL.

ENORMOUS INCARCERATED AND SUBSEQUENTLY STRANGULATED INGUINO-SCROTAL HERNIA, PROBABLY CONGENITAL: DIFFICULTY OF DIAGNOSIS: OPERATION: VIOLENT PERITONITIS: RECOVERY.

UNDER THE CARE OF MR. WILLIAM STOKES.

(Reported by Mr. JAMES ROSS.)

FROM the very unusual and extraordinary symptoms and physical signs in the following case of hernia, it must be admitted that an accurate record of it is of considerable value in a practical point of view.

Thomas F., æt. 30, by occupation a cooper, was admitted into Mr. Stokes' wards in the Richmond Hospital on the 8th of last June. He stated that he had a hernia on the right side as long as he remembers, and that he was always able to reduce it until two weeks previous to his admission into hospital. He stated that when it was reduced, there was a great thickness of the scrotal coverings remaining which was not so on the left side, and that the testicle was always much smaller on the affected side. The symptoms of strangulation, however, did not appear to supervene until the day before his admission. There was frequent vomiting and hiccough, constipation, great pain and tenderness over the lower part of the abdomen, which were especially acute in the situation of the external ring.

On examination a large scrotal tumour was found, of great weight, the upper half of which was tympanitic on percussion, the lower half absolutely dull. There was great tension of the skin over the tumour, which was somewhat lobulated and irregular on the surface. There was *little or no impulse on coughing*, and on moving the tumour suddenly from side to side, or from before backwards *a loud splashing sound could be distinctly heard*, like that of hydro-thorax, indicating the admixture of air and water within the tumour. On examining it with reference to transparency, none whatever could be found.

Shortly after his admission, he was put under the influence of chloroform, and the taxis carefully tried, and though Mr. Stokes failed to reduce the hernia, he thought he succeeded in diminishing the size of it somewhat. At all events, some of the symptoms of strangulation—viz., the vomiting and retching, and the violence of the abdominal pain, *subsided after the taxis*. In the evening, 8 P.M., the scrotum became again very much distended, causing much pain from the tension. There was also retching and hiccough. These symptoms, however, under the influence of anodynes, enemata, hot fomentations, and the warm bath, towards morning completely subsided. The same state of things recurred next day.

Div. in pill 80. Vt. dict.

June 12.—The bowels were moved slightly on the 11th. Pulse quiet. Patient able to take light food, and very little tenderness about the abdomen or scrotum.

13th.—The symptoms of strangulation recurred with great violence. Mr. Stokes got the following message from Mr. Ross, his resident clinical assistant:—"The patient with hernia in No. 7 ward has been very ill during the night, vomiting set in at two A.M., and has continued at frequent intervals since then. He is perspiring profusely." On Mr. Stokes' arrival, he found that the alarming symptoms the patient had during the night and early morning, had greatly subsided. He was in a state of great prostration, perspiring profusely, but the vomiting had stopped, the constipation which had now lasted since the morning of the 11th continuing. The tenderness and pain over the abdomen and scrotum had also to a great extent subsided. The pulse was 76, and very weak. At this juncture, Mr. Adams kindly saw the case with Mr. Stokes, and was of opinion that although the patient's symptoms were decidedly alarming, and the prognosis unfavourable, yet, that under existing circumstances, the symptoms of strangulation having to a great extent subsided, immediate operation was not called for. It was then determined that a consultation should be held at 5.30 P.M., the patient to have in the meantime a full enema, and morphia and hydrocyanic acid internally. At 5.30 P.M., the patient was found considerably better. He had only had during the day two slight attacks of retching. The tumour was not nearly so tense, and the tenderness in the abdomen greatly better. He was still in a very weak and exhausted condition. The enema had come away, but there was no feculent motion from the bowels. Mr. Stokes then agreeing with his colleagues, considered it would be better again to defer any operative interference until he saw what course things were going to take, and accordingly it was agreed to meet again to see the patient at 10.30 P.M. In consequence of this unusual, and extremely interesting case, many other eminent surgeons in addition to Mr. Stokes' colleagues, came to see this case. Among them may be mentioned Mr. Porter, President of the Royal College of Surgeons; Mr. Fleming, Mr. Collis, Dr. Wharton, Mr. Croly, Mr. O'Grady, &c.

The difficulty of diagnosis in this case as to whether namely, it was one of simple strangulated congenital hernia, or whether the case was one of a small hernia into a large previously existing hydrocele of a hernial sac, arose from the existence of the following symptoms and appearances:—

1. The absence of all impulse in the tumour on coughing.
2. The intermittent symptoms of strangulation.
3. The great weight of the tumour.
4. The loud succussion sounds.
5. The absence of translucency in any part of the tumour.
6. The comparative freedom from pain in the vicinity of the ring.
7. Absence of all abdominal fulness.

Many of these symptoms and signs were characteristic of the rare form of hernial complication, known as "Hydrocele of the hernial sac," which, as Dr. Fleming has remarked, occurs generally in adults in early life, with large not fully reducible scrotal herniæ, or the rarer variety named "Congenital inguinal hernia."

The chief difficulty, however, in determining the exact nature of the case, and, consequently, the line of treatment to adopt, arose from the intermittency in the symptoms of strangulation, and the loud succussion sounds.

At 10·30 P.M. the symptoms of strangulation having again supervened, and with greater intensity than at any time previously, Mr. Stokes decided upon performing the ordinary operation for strangulated hernia. On making the usual incision over the external abdominal ring, and dividing layer after layer of fascia down to the sac of the hernia, the opinion which was given, in the first instance, by Professor R. Smith, was found to be absolutely correct. There was no hydrocele of the hernial sac, and the great mass of fluid and air which gave the succussion sounds, so unusual in hernial tumours, were *within*, not *external* to, the intestine, and the enormous scrotal tumour was composed entirely of a mass of intestines.

On arriving at the peritoneal sac, Mr. Stokes passed his finger up to feel for the constriction which caused the strangulation, and found that it occurred at the external abdominal ring, and that it was caused, not by a narrow cord-like constriction, but, which is also unusual, by a broad, flat, riband-like constriction.

Mr. Stokes was very anxious in this operation to reduce the hernial tumour without opening the peritoneal sac, in consequence of the large size of the tumour, and the recent and intermittent strangulation of the intestine. However, in passing his finger up to the constriction he must have pushed a portion of the sac before it, for a quantity of fluid came welling up from the bottom of the wound, the very moment the stricture was divided. After this a good view was obtained of the intestines. They were found considerably congested at the seat of the stricture, but everywhere else they appeared quite normal and healthy. Fully three feet, or perhaps more, of small intestines were in the scrotal tumour, and the reduction of this vast coil of intestines was not accomplished without very great difficulty.

After the operation the patient got a powerful anodyne draught, and one grain of opium every third hour during the night. Also, strong beef-tea iced.

14th.—He slept very well during the night, and at 8 P.M., this morning, his bowels were moved. He took some milk and egg this morning. Pulse 112. As the day advanced the pulse became full and bounding, and rose to 120 in the evening. Very violent spasms in the abdomen set in. When each spasm subsided, Mr. Ross could hear a loud gurgling noise, after which the patient expressed himself much relieved. There was great tenderness and pain in abdomen, especially above the right groin. The patient was put on calomel and opium, and twelve leeches were applied to the right side of abdomen. After the application of the leeches, the bleeding was encouraged for some hours by hot fomentations.

15th.—Pulse 112, compressible. There is persistent vomiting, but scarcely so much tenderness over the right side of abdomen. The right testicle is highly inflamed. The patient's countenance wears an anxious expression. He is in a state of great prostration, and lies with his legs stretched at full length. The abdomen is tympanitic and very tender. He passes urine freely, it is high coloured; bowels not moved since yesterday. Mr. Stokes ordered the calomel to be stopped, but a grain of opium to be given every third hour, and strong mercurial ointment to be rubbed into the axillæ and smeared on a large linseed meal poultice to be applied to the abdomen. Twelve more leeches to be applied to the abdomen.

16th.—The spasms have diminished in frequency and intensity, and the patient slept pretty well during the night. The tenderness in the abdomen is somewhat diminished, but it is distended to a great extent. He frequently passes flatus, but bowels not moved since the 14th. There is great thirst, the tongue is now red, but moist. Pulse 100. The gums are slightly touched by the mercury. Although he has taken a grain of opium every third hour since the operation, it has not had any effect, except making him drowsy and taking away his appetite. The pupils are not contracted.

17th.—Pulse 90. Patient had a slight attack of syncope at 7 o'clock this morning. The distension of the abdomen is considerably less than it was yesterday, but there is a good deal of tenderness still. There is less vomiting now, and his appetite is returning. He took a little calve's-foot jelly and iced brandy this morning. Last night prussic acid was given to allay the vomiting, and it proved very efficacious. The mercurial inunction was ordered to be stopped. Opium reduced to half a grain every third hour. Six leeches to be applied to the abdomen, close to the wound.

18th.—The anxious expression of the face is almost gone, and he has had very few spasms during the night. He is able to take light food to-day. His bowels still not moved, but a great deal of flatus came away. There is very little thirst. The testicle is not so painful, but is still enlarged. Pulse 90.

19th.—Expression of face greatly improved. He has lost all his anxious look. The abdomen is now very flat, and there is very little tenderness about it. In the evening the bowels were moved four times, the evacuations being partly solid. Pulse 86. Opium to be stopped.

20th.—Still progressing very favourably, but the enlargement of the right testicle is undiminished. Bowels moved twice.

21st.—Improving rapidly. All medicine to be discontinued.

July 2nd.—Wound very nearly healed. Bowels perfectly regular. Appetite excellent. No trace of any abdominal pain or tenderness.

CITY OF DUBLIN HOSPITAL.

CASES OF ONYCHIA, WITH OPERATION FOR REMOVAL OF THE DISEASED NAIL.

UNDER THE CARE OF MR. CROLY.

CASE 1.—E. R., a healthy-looking boy, aged 12 years, was admitted into the City of Dublin Hospital, suffering from Onychia of the great toe of the right foot.

The disease commenced six months previously, and was caused by an injury, a person having stood on her bare foot.

Appearance of toe.—The ungual phalanx is clubbed; the nail is black and shrivelled; there is much fœtor, and an ichorous discharge from the region of the matrix, where a foul ulcer is observed. The part is exquisitely painful. Various remedies were adopted before the patient sought for hospital relief.

Operation.—A freezing mixture consisting of ice and salt was applied to the toe by means of a bladder, and when the part was sufficiently frozen Mr. Croly seized the nail in a dissecting forceps, and with a scalpel rapidly dissected out the entire nail, taking care to remove every portion of it, to prevent a return of the disease. The freezing mixture caused considerable pain, but none was felt during the operation.

An iced lotion was applied to the part, and the subsequent treatment consisted in touching the raw surface with nitrate of silver, and circular strapping with soap plaster.

The ulcer healed, and the patient was discharged cured.

Case 2.—A. B., a boy, aged 6 years, had Onychia of the index-finger of the right hand. The disease commenced a month previously, and was attributed to an injury—a window-sash having fallen on the finger. The ungual phalanx presented the characteristic clubbed appearance indicative of Onychia. The nail was curved, black, and shrivelled; the discharge was ichorous and fœtid.

The patient having been placed under the influence of chloroform, the nail was dissected out, and the ulcer was treated as in the preceding case.

Recovery soon followed.

Case 3.—P. C., a boy, aged ten years, had well-marked Onychia in the great toe, of six months' duration. The disease originated from a cut of a piece of glass.

The toe was clubbed, and there was a foul ulcer at the matrix. Discharge fœtid and thin; patient suffers much pain. On measurement the diseased toe was found to be four inches in circumference at the clubbed extremity—the sound toe measuring two and a-half inches at the corresponding part. The diseased toe was two inches in length—the sound toe one and a-half inch. The patient was fully chloroformed, and the nail dissected out. Carbolic acid lotion was used as dressing, and the parts soon assumed a healthy appearance.

Case 4.—A man, aged 40 years, suffering from Onychia of more than four months' duration, in the second finger of the right hand; the patient had been treated by lotions and other local applications without relief. The part having been frozen with ether, by means of the spray-producer, the nail was dissected out; the ulcerated part was subsequently dressed with "Condy's fluid," and the disease was cured.

Mr. Croly, in making clinical remarks on these cases, observed on the characteristic appearances of this very painful and tedious disease, and on the successful result of the removal of the *entire* nail from the matrix, as even the smallest portion, if allowed to remain, is surely followed by a return of the disease. Having tried in these several cases, respectively, the freezing mixture—ether spray, and anæsthesia by the inhalation of chloroform, Mr. Croly gave a decided preference to the latter, as the local application of intense cold on a highly inflamed part produces excruciating pain. He, however, recommends iced lotions, subsequently to operation, with a view of reducing the inflammation.

In connection with this subject, Mr. Croly also referred to Onychia maligna (described by Wardrop, Abraham Colles, and other surgical authorities) and the appropriate treatment for that special form of the disease.

Foreign Medical Literature.

TRANSACTIONS OF THE SWEDISH SOCIETY OF PHYSICIANS.

Translated from the *Hygiea* for October, 1867, by

W. D. MOORE, M.D.Dub. et Cant., L.K.Q.C.P.I., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

AT a meeting held on the 10th September, 1867, Hr Blix communicated the following case of ulcerative endocarditis of the tricuspid valve:—

Mrs. E. Q., aged 31, was admitted into the Seraphim Hospital on the 20th June, 1867, and died on the 1st of August following.

The patient had been delivered in the General Lying-in Hospital on the 13th April. During pregnancy she had been tolerably well until the 6th January, when hæmorrhage took place at night from the uterus, subsequently returned several times, and increased in frequency towards the end of her term. On admission she was extremely pale and anæmic. Delivery was completed by operation, in consequence of placenta prævia and cross-presentation of the child. For the first few following days her state was particularly unsatisfactory, but she afterwards improved, and her confinement proceeded quite normally. She was dismissed on the 26th of April "at her own desire, being then in a very anæmic state." The report of her case will be found in the July number of the *Hygiea*, communicated by Dr. Netzel in a paper "On the origin and development of placenta prævia totalis." During her subsequent stay at home the patient was very languid and weak, though not incapable of lighter kinds of work. In the early part of May she observed that her feet and the lower part of her legs began to swell; the swelling, however, continued only six days, was not considerable, and totally disappeared on rest in the recumbent posture. In the course of a month her state was, with the exception of the languor and weakness, which continued almost unaltered, tolerably good; but on the 6th June she was quite suddenly attacked with violent rigors, which, during the fourteen days she afterwards remained at home, were repeated regularly four times daily, and were usually followed by copious perspirations. Her state of weakness meanwhile increased extremely, on which account she sought admission into the Seraphim Hospital. On her admission, her strength was much depressed; she could scarcely raise herself in bed; her countenance presented a death-like paleness. The body was much emaciated. There was no swelling of the extremities or other parts. Her skin felt dry: its temperature varied so that between the attacks it was usually [illegible]·8°, while during and immediately after them it was 10[illegible]. In the lungs there was nothing to remark upon except [illegible] in the right clavicular region, [illegible] expiratory murmur [illegible] mixed with moist râles. There was [illegible] cough, with catarrhal expectoration, mixed with some yellow lumps. The sound on percussion in the cardiac region was normal. On auscultation there was heard both over the apex and base of the heart, and also over the intervening parts, a strong and particularly protracted systolic bellows-murmur almost drowning the diastolic sound, which was heard pure but weak. Loud *bruits de diable* were audible over the cervical vessels. The pulse was extremely small and rapid. The liver was considerably enlarged, projected a couple of inches below the margin of the ribs, where it could be distinctly felt. The spleen was not enlarged. The appetite was tolerably good; the bowels were regular; the urine was free from abnormal constituents. In the uterus and its appendices there was nothing to remark. With respect to the intermittent attacks, it was observed that they occurred regularly four times a-day; only two days were they wholly absent, and during three days they were only two or three in number. They occurred always during the day-time; at night the patient for the most part slept well; they did not occur at definite times, but varied—two sometimes taking place in the forenoon, and two in the afternoon; while at other times one or none was observed in the forenoon, and three or all four in the afternoon. Their duration and intensity also varied from fifteen minutes to two hours; they exhibited themselves at times as slight chills, at others as severe rigors. During the attacks the respiration was always very much hurried, while the pulse was extremely small and quick. Between the attacks —which were invariably followed by profuse perspiration—the patient felt perfectly free from suffering, but was languid and weak. Fourteen days after her admission she coughed up, during a violent intermittent attack, some tablespoonfuls of light-coloured frothy blood, after which the expectoration had for some days a sanguineous admixture, which subsequently, however, quite disappeared. Quinia seemed to have not the slightest effect on the attacks; it was given repeatedly both in full and in divided doses. She was at the same time treated with tonics and stimulants. Upon this plan her condition somewhat improved, her strength having increased so far that she could occasionally remain up dressed between the attacks. Without any further change having taken place on the preceding days in her state, she was quite suddenly attacked on the morning of the 1st of August with severe dyspnœa and palpitation of the heart; cold perspiration broke out over her face, which soon assumed a livid hue; tracheal râle began to be audible, and she died after an hour's agony.

Post-mortem appearances.—Body much emaciated. On opening the thorax both lungs were found perfectly free in their cavities; the left exhibited no changes except œdema in its upper lobe, hypostatic sanguineous congestion in its inferior, and slight bronchial catarrh; the right was somewhat swollen and doughy to the touch. On dividing its parenchyma the latter grated slightly under the knife, and the cut surfaces, which presented an uniformly reddish-grey appearance, rapidly covered themselves with a thin fluid containing but little air, which could be abundantly pressed out from the parenchyma. In the apex of the upper lobe were found some encysted and calcified foci, around which the pulmonary parenchyma was sclerotic. At the same time more or less solid fibrinous plugs, partly white or whitish-grey, partly reddish-grey, were visible everywhere on the cut surfaces in the divided branches of the pulmonary artery, generally completely filling the calibres of the vessels. On slitting up the pulmonary artery it was seen that both in its principal trunk and also in the majority of its branches, so far as these could be traced—nearly, in fact, as far as the surface of the lung—the vessel was completely filled with thrombi, which in one part, and chiefly in the branches [illegible] to the upper lobe, consisted of a whitish mass, in some [illegible] breaking up, in others more solid, and attached to the [illegible] thickened vascular wall; in others, were composed of [illegible]-red, laminated, fibrinous masses, completely filling the [illegible] of the vessels and loosely adherent to their walls. The [illegible] in the principal trunk was of a bluish-red colour and [illegible] consistence, did not completely fill the vessel, and [illegible] in a tapering manner immediately at the opening of [illegible] into the auricle. The few branches of the pulmonary [illegible] which were not obstructed were pretty considerably [illegible] but did not exhibit any change in their walls. In the [illegible] were no thrombi. The pulmonary pleuræ of both [illegible] studded with some greyish-white tubercles [illegible] heads of pins. The heart was of the usual size, [illegible] the touch. The muscular substance, espe-[illegible] ventricle, was rather more brittle than is nor-[illegible] presented a yellowish discolouration. The [illegible] and pulmonary valves were of healthy appearance; but the tricuspid exhibited the following changes:—The right anterior lobe (Luschka) was in parts thickened, somewhat rugged and uneven on its outer surface; on its inner it was loaded with an irregularly-shaped fibrinous lump, nearly the size of a Spanish nut, adhering intimately to the thickened part of the lobe of the valve from its free margin to one and a half lines from its attachment to the muscular wall; the fibrinous mass was of a greyish-white colour, tolerably solid and hard, but in spots, as it were, excavated, and there in a breaking-up condition. Some of the chordæ tendineæ going to this lobe were cut off and lay retracted and thickened towards their papillary muscles; the infero-posterior lobe was in one half perfectly normal, but the other half, lying against the right anterior lobe, exhibited a considerable loss of substance, as there remained of it only a patchy ridge from one to one and a-half lines in breadth, springing from the ventricular wall with thick, uneven margins in a state of disintegration. The chordæ tendineæ which are inserted on this part of the valve were also cut off and lay retracted, with small swellings on their free extremities. The left posterior lobe was normal.

The liver was considerably enlarged; its capsule was smooth and shining. The surface of section was even, of a bluish-red colour, quickly becoming covered with fluid blood, which, especially when the parenchyma was pressed, ran out in great quantity, both from the larger and smaller blood-vessels. The acini were small, with bluish-red centres and greyish-yellow peripheries. The spleen, kidneys, and intestinal canal presented nothing remarkable. The uterus and its ligaments were quite normal both in situation and size. In the uterine veins were found thrombi, which could be traced into the hypogastric, and further into the iliac and crural veins, and into the vena cava inferior, though in all these vessels they exhibited very different appearances. In the uterine veins, of which only two or three at each side of the uterus contained thrombi, the latter were of a greyish-red colour, tolerably solid and loosely adherent to the vascular walls, which in general presented no change. The hypogastric and iliac veins were considerably thickened as to their walls, and were strongly contracted; the iliac veins were as thick as a small lead pencil, and on being slit up were found to be filled with greyish-white fibrinous cords, which on microscopic examination appeared to be composed of ordinary young connective tissue. At the junction of the iliac veins with the vena cava inferior, which did not exhibit any alteration in its walls, the thrombous mass assumed a reddish-grey colour, was of rather loose consistence, though it nowhere seemed to be in a state of disintegration, and filled the vessel only incompletely, being closely adherent to the posterior wall. It extended for ten centimètres (nearly four inches) up into the vena cava, and terminated quite abruptly, sending off a fusiform lateral offshoot. In the crural vein, and in several of the larger veins opening into it, were greyish-white and greyish-red fibrinous masses, in general in a state of disintegration, and loosely attached to the thickened vascular walls.

This was therefore a case of ulcerative endocarditis of the tricuspid valve, and it was the second instance of the kind which, within a comparatively short time, had occurred in the hospital. The first is detailed in the September number of the *Hygiea*—a circumstance of great interest when it relates to a disease which is so extremely rarely met with.

In this, as in the former case, the diagnosis of cardiac disease had not been made, the change in the valve being discovered first at the post-mortem examination. As appears from the history of the case, the patient presented symptoms of well-marked anæmia, and under such circumstances one was naturally quite satisfied to explain the systolic accessory murmur perceived over the heart as accidental, the attention not having been specially directed to the tricuspid valve, so as to induce a closer investigation of the cardiac sound derived from it. That, however, the great fibrinous mass on one lobe of the valve must have produced an accessory sound is quite natural, and that the considerable loss of substance found in another lobe, must have given rise to insufficiency, is also a matter of course. In addition to anæmia, pulmonary tuberculosis was diagnosed for reasons which the physical investigation, the course of the disease, and other circumstances suggested, and which were exceedingly strengthened by the expectoration of blood. Tubercles were, in fact, discovered in the lungs, but, as the post-mortem examination showed, only some miliary eruptions on the pleura pulmonalis. The case was, however, in many respects obscure, and not the least so from the frequent intermittent attacks which could not be accounted for either by the anæmia or the tuberculosis; the examination of the uterus did not furnish any standing points. It was only the post-mortem investigation which yielded the necessary explanation of all. The formation of thrombi in the vessels of the pelvis, as well as in the vena cava and the crural veins, is of course connected with the accouchement, was a puerperal process; the appearance of the thrombi is by no means opposed to this view, but it is very curious that this extensive thrombosis should take place without other symptoms than a slight swelling of the feet and legs, which, after six days, completely disappeared.

The intermittent attacks coincide with the occurrence of the ulcerative endocarditis and the formation of thrombus in the pulmonary artery; nor is the fibrinous mass, nor the appearance of the valves, nor are the thrombi themselves opposed to this view. The very sudden death of the patient was undoubtedly connected with the fresh coagulation in the principal trunk of the pulmonary artery, which, if it did not completely cut off, yet considerably limited the supply of blood to the few non-embolised and dilated branches of the artery.

In connection with this case, Hr Bruzelius spoke briefly of the different diagnostic value of accessory sounds, accompanying the first and the second sound of the heart.

◆

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

Royal College of Physicians, London.

Saturday, June 27, 1868.

Dr. Burrows, President, in the chair.

DEPARTMENTAL BUSINESS.

The President read a memorial from the clerks in the office of Medical Council, Messrs. Bell and Roope, asking for an increase of salary in consequence of their long years of service, and the great increase of work now devolving upon them. The President handed the memorial to the Chairman of the Finance Committee to report thereon.

Dr. A. Wood, as Chairman of the Business Committee, begged to suggest that, in order to give the fullest attention to the subjects appointed for consideration by Committees, and to facilitate the business of the session, there should be no meeting of the Council on Monday, but that the members should meet on that day from twelve till six o'clock for sittings of the following Committees:—The Visitations of Examinations, Vaccination, Medical Education, Finance, Lunacy, Primary Education, and the Pharmacopœia.

Sir Dominic Corrigan seconded the resolution, agreeing that it would greatly expedite the business before them if the whole of that day were devoted to committees as suggested. With this the Council entirely concurred.

DIPLOMAS IN STATE MEDICINE.

Dr. Acland, pursuant to notice, then rose to move—

"That a Committee be appointed to report on the steps proper to be taken (if any) for granting Diplomas or Certificates of Proficiency in State Medicine, and for recording the same in the 'Medical Register,' due regard being had to the interests of existing Health Officers in the several parts of the kingdom."

He said the subject had been introduced by him last year, but he was induced to withdraw its consideration from press of business, and for other reasons well-known to the Council. Now that it was stripped of some of the objections by which it was then surrounded, and the essence of the whole matter left, in his mind it was one of the most important subjects that could occupy the attention of the Council. It was unnecessary for him to enter into details; State medicine, or as it was otherwise called, preventive medicine, some few years since had no existence whatever; but now, thanks to Dr. Rumsey, whose labour to make it recognised had been remarkably successful, and also to the more extended study of the subject, it had now become a most important and useful branch of knowledge. It was generally supposed that if a person's name was on the register, he was conversant with this subject, still he doubted if it were so, and although he did not think the study of it should be added to those already on the curriculum; he, nevertheless, held that it might be advantageously placed as one of the optional subjects, so that medical practitioners should have the opportunity afforded them of studying it, if they so desired. He knew of cases where members of the profession had set about it manfully, and had even diminished their income in consequence, because the public imagined they were incapable of mastering the difficulties attendant on the direct line of their professional sphere, and had stooped to an indirect and an inferior course in their estimation. But was this an inferior branch of knowledge, he argued that it was far otherwise; sanitary measures, medical jurisprudence, &c., were of the highest importance, and instead of being *second* to the ordinary subjects of education, he looked upon them as even superior, as everyone must admit that "prevention is better than cure." He should be glad to see medical men as health officers in all parts of the United Kingdom, and that a special certificate should be granted them as to their capabilities to advise on all matters connected with this department. During the meeting of the British Medical Association in Dublin last year, which was a great success, owing to the kindness and urbanity of the President, Dr. Stokes, and the genuine and hearty welcome with which their Irish brethren received them—a successful attempt was made to give to the meeting a national scientific air. Amongst others, the paper on "State Medicine" by Dr. Rumsey, was read, which eventually led to a committee being appointed in conjunction with the Social Science Association, to wait upon the Government in reference to this important subject. He therefore hoped that a committee would be appointed to consider the claims of this special branch of education, and that they should report thereon to the Council.

Dr. Stokes, in seconding the motion, held that it behoved the Council to watch narrowly the interests of the profession. Strict supervision was necessary, as the subject of state or preventive medicine in a medico-legal view was of the utmost importance. Nothing was more common than the sneers and uncharitable remarks indulged in by clever lawyers and the public, when a medical man was called upon to give evidence in a case in court, because he was unable exactly to determine the cause of death; he was snubbed and had to retire, conscious of his inability to give any satisfactory answer to the cross-questionings to which he was subjected. And why was this? simply because this portion of his education had not been attended to. The time had however now arrived, when this branch must receive special legislation, and he hoped the time was not far distant when—instead of the practitioner's ignorance of this subject being a cause of concealing crime—he would be able at once to determine, when called upon, the point under investigation.

After further remarks from one or two speakers, the motion was carried *nem con*, the committee consisting of Dr. Smith, Dr. Stokes, Dr. Christison, Dr. Rumsey, Dr. Parkes, Dr. Acland, Dr. Thomson, and Dr. Paget. An instruction to the committee by Mr. Hargrave, seconded by Dr. Alexander Wood, was ultimately withdrawn by consent.

SECONDARY SCHOOL EDUCATION.

The following was then moved by Dr. Storrar:

"That, having regard to the importance of improving the general education of persons entering on the study of Medicine, it is incumbent on the General Council to petition both Houses of Parliament, praying for early legislation on the subject of secondary education in schools; that it be referred to the Executive Committee to prepare petitions to the Houses of Lords and Commons; and that the President be authorized to sign and affix the seal of the Council to them, and take measures for their presentation."

Dr. Storrar commenced by saying that if he were asked what he meant by secondary education, he should define it thus: primary education he understood to mean reading, writing, arithmetic, and the English language; secondary education when a youth was taught the classics, mathematics, languages, &c. It was a conventional term, but he believed one generally accepted. The principles of general education had been so often discussed, that it was only necessary for him to take a retrospective glance at what had been done, and what could be devised to improve it. He would have the present standard raised, and see that it was honestly maintained. He would rather youths were kept at their preliminary studies a year longer than was generally the case, so that their intellects might be better formed for the transition to the higher attainments. He would shut out those men who were incapable, from whatever cause, to come up to this standard, telling them honestly the profession they were better fitted for than that of medicine; but, on the other hand, they would do well to secure all young men who had received a good general education, with a capacity to enter on their professional studies, and having attained this object, to steer them through the higher branches required by the examining bodies. He had the honour to be engaged on the recent Royal Commission, appointed to inquire into the conduct of public schools, and the impression upon his mind was, that endowed schools were often, by their mismanagement, great obstructions to the well-being of the pupils. There were no less than 800 endowed schools in the kingdom, with endowments varying from £5 to £40,000 per annum, the aggregate being considerably over £200,000. He might state that a grammar school was generally understood to mean a classical school, where the system of secondary education on which he was speaking was taught. Some of these schools he had found to be very good, others indifferent, others downright bad, and a few, though it might seem an anomaly, were not schools at all. On the subject of general or secondary education in England, Ireland, and Scotland, they all agreed that it was not in the satisfactory state they could desire; he, therefore, proposed that the Council by their actions, should endeavour to strengthen the hands of the Legislature who were endeavouring, and were willing, to do all that was possible in this respect.

Dr. Alexander Wood had great pleasure in seconding this motion. From his own experience as an examiner in the Edinburgh schools, he must confess that to improve the education of youths in the present constitution of schools was simply impossible. It was deplorable to see so much seed wasted because of the unprepared state of the ground on which it was sown. He hoped the Council would raise their voice towards dragging the present unsatisfactory condition of general education into a new existence. There was one school which he might mention as an exception in Scotland to the general rule—that was the University of Aberdeen. It was so admirably managed, and the most essential portions of their education were so thoroughly impressed on the minds of the students, that he had no hesitation in saying he could distinguish an Aberdeen graduate from any other by the superior way his mind had been prepared. He would extend this system throughout the country, and men would be able to take their stand in life on a much higher platform.

Dr. Bennett considered the subject of great importance, but suggested that it should be referred to the committee sitting on Dr. Andrew Wood's motion, to which the question belonged.

Sir Dominic Corrigan could not give his adhesion to the project of a petition to Parliament. If the subject was worthy their attention, and action was to be taken on it, they should legislate for themselves; because, from past experience of the Council on Parliamentary petitions, little could be expected from that quarter. He agreed that the present state of our young men demanded their most serious attention, and for that reason he objected to wait the result of a petition. His opinion was that a committee be immediately appointed to inquire in what way the standard of general education could be raised; and he would extend the inquiry not to public schools alone, but to private ones also. He begged to propose an amendment to that effect.

Dr. Andrew Wood remarked that something must be unquestionably wrong in the system which produced such results as came under his observation, instancing some very extraordinary answers that had been given to the simplest questions by pupils when under examination.

Dr. Apjohn would also vote against the motion, as he considered that the Council had already done what they could for education, and this was a step out of their province.

Mr. Hawkins was of the same opinion, and suggested that as Government was taking the entire subject of education up, it would be unwise at present to interfere.

After a few remarks from Dr. Storrar,

The motion was put from the chair and agreed to by a majority of one.

The Council then adjourned.

Monday, June 29.

The Council were engaged the whole day in committees on the subjects mentioned in Friday's proceedings.

Tuesday, June 30.

REGISTRATION OF STUDENTS.

Dr. Embleton moved—"That a committee be appointed to consider the returns of examinations from the licensing bodies, and the registration of students."

Sir Dominic Corrigan objected to the motion, because the registration was found to be utterly useless in practice, and in [illegible] such regulations would be laughed at.

Dr. Andrew Wood hoped the Council would express themselves in favour of the appointment of a committee, and not be deterred therefrom because they were told they might be laughed at.

After a few remarks from Dr. Paget, Dr. Alex. Wood, and Professor Syme, the motion was carried *nem. con.*

PRESENTATION OF THE "REGISTER."

The following motion by Dr. Paget—"That in future every person whose name shall be entered for the first time in the 'Medical Register' shall be entitled to receive on application the published copy of the 'Register' for the year in which his name has been entered," was also agreed to with but little discussion.

DEPUTATION FROM THE BRITISH MEDICAL ASSOCIATION.

The deputation from the British Medical Association—which consisted of Dr. Sibson, president; Dr. Waters, Mr. Nunneley, Mr. Southam, Dr. Hy. Simpson, and Mr. Watkin Williams, secretary to the association—was then formally introduced to the Council, the president stating that he should reserve to himself the right, on behalf of the whole Council, to use what interrogatories he deemed necessary, or should be suggested to him in writing by any member of the Council, so as to elicit anything that might be necessary for them to know, and what importance they should attach to the memorial which was brought for presentation.

The President then inquired whether it was the memorial of the whole body of the Medical Association, or simply emanated from the council.

Dr. Sibson replied that in spirit it emanated from the whole body of the Association; and in answer to some other questions of the president, gave a brief account of the manner in which the British Medical Association had come to the resolution to present this memorial to the Medical Council. The resolution was carried almost unanimously at a very large meeting in Dublin, presided over by Dr. Stokes. Addressing the president, Dr. Sibson said—Let me now call your attention to the spirit which animates the Association towards this Council. It was, so to speak, in taking steps to give aid to this Council in its work, and in token of our great approval of the work done here by the Medical Council, that this proposal originated. Let us look for one moment at the constitution of the Council as it now stands. I may say there is no single member of it that represents what may be termed the body of the profession. There are most important members sent up from the various universities, who represent truly the education of the profession; there are most important members sent up from the various bodies who confer power to practise medicine; and although some have said that it is possible those gentlemen may be influenced by the bodies they represent, to the disadvantage of the true interest of the medical education, the Association that I have the honour to represent do not entertain such views, but are satisfied that every gentleman composing this Council always has done his utmost to promote the welfare of the profession, quite irrespective of the individual body that he represents. We therefore take no exception whatever to the elements that compose the existing Council. On the contrary, they are the very elements we were the first to recommend; and if we had the work to do over again, where could we go to find a body of men so capable of supporting that which is best worthy of support in the profession as those who form this Council? I do not allude to individual members, but I allude to those bodies who are certain almost to send here their very best men. But may I suggest to you that if taxation and representation ought to go together, the body of the profession has an inherent right to be largely represented on this Board. Observe, sir, that every pound that comes into the coffers of this Council comes not from the corporations or from the universities, or from the Government, but from the general practitioners and the physicians and surgeons of the kingdom. And as I have named the Government, it is only due to the Government to say that it has always sent to this Council an admirable body of men; but it cannot be said that, admirable as they are—high in education, well-known as promoters of the public health—that they represent the profession. But although we have a large claim to be represented, the Association has no desire whatever to obtain a preponderating weight of votes in this Council, but only in a minority of one-fourth; and why we have asked for eight in the existing state of things, if the Board should be, in consequence of the addition—supposing it to be made—considered too numerous, we should consider if the numbers were reduced that that reduction should apply equally to those representatives of the profession as to the representatives of the public bodies. Dr. Sibson then pointed out a few of the advantages he thought would accrue by the proposed change.

After a few remarks from Dr. **Waters** and Mr. **Nunneley**, the deputation thanked the President and Council for their attention, and withdrew.

REPRESENTATION OF THE PROFESSION.

Dr. **Andrew Wood** then moved the following resolution :—'That the Medical Council take into consideration its present constitution with a view of determining whether it be not advisable that it should be placed on a more popular basis, by the addition of a certain proportion of members to be chosen directly by the suffrages of registered practitioners." He then said he was afraid he should be obliged to occupy the time of the Council longer than he had previously done during the session, as he thought upon so fundamental a question, the Council should not decide *pro or con*, without most careful deliberation. He regretted that circumstances should have devolved upon him the duty of bringing forward the question. It had been proposed that the interests of the profession, and of the corporations and universites connected with the education of the profession, should be handed over to a Crown Council to be composed of about twelve members to regulate the profession. That was the purport of Lord Elcho's Bill which he was happy to say the profession had succeeded in defeating. The constitution of the Council afterwards agreed upon was improved in the Bill brought in by Mr. Cowper, and Mr. Walpole, and remains to this day as then laid down. They had heard from the deputation that the British Medical Association were the first to engage in medical reform, but while admitting that they had contributed to the passing of the Medical Act, he absolutely denied that they were mainly the cause of it. He then drew attention to the present constitution of the Council. England was represented by eleven members, of whom four sit for universities, three for medical corporations, and four for the Crown; Scotland was represented by six members—two for universities, three for medical corporations, and one for the Crown; Ireland was represented by the same number and in the same proportion, so that there were eight university members, nine of medical corporations, and six crown members, which with the President was the total number of the Council. The Council when founded had the almost universal approbation of the profession. It was not objected to by the British Medical Association, they only suggested that the Crown nominees should constitute one-third part of the Council. One great object why the British Medical Association were so anxious the Crown nominees should be numerous was this—that they might be representatives of the general practitioners. He believed in the very first appointment made by the Crown there were two representatives of the general practice of the country in the persons of Sir Charles Hastings, who he believed at that time was President of the British Medical Association, and their esteemed and lamented friend Mr. Teale. Since that time the only representative of the general practice sent by the Crown was his friend Mr. Rumsey—so that if there were expectations excited at that time, that the Crown nominees were to be the means of representing general practice, those expectations have not been fulfilled. He did not think they had any reason to find fault with the nominees sent by the Crown, and they had no reason to wish that we should get rid of them. He had seen in some of the medical journals the proposition made, that as the crown paid nothing for the expense of the Medical Act, they should get rid of the Crown nominees, and convert them into popular representatives of the general body of the profession; but that would be no part of the scheme which he was about to propound, that the crown nominees should be diminished. It was right, especially after what they heard to day, that they should look at the *personel* of the Medical Council as it at the present moment exists. There are many misrepresentations abroad in regard to this, and the cuckoo-cryatile being continually sounded, that general practice finds no representative in the Council. It was quite true that general practice did not find any direct representation such as had been proposed to them and such as he was about to propose; but there were general practitioners upon that Council, and how the interests of general practitioners were looked after would appear from the enumeration that he was about to give them. He found, taking the 24 gentlemen who were sitting round that table, that 8 of them were pure physicians, 3 were pure surgeons, and 8 were general practitioners—men engaged at ordinary practice of their profession, who were neither consulting physicians nor consulting surgeons. They had had three scientific teachers who were not in actual practice, and, he needed scarcely add, their presence amongst them was a most valuable element; and that they possessed one gentleman experienced in everything—in teaching, in examining, and in practice, he alluded to Dr. Parkes. It was right that that should go forth, in order that it might be proved what general practice was represented to a certain extent upon that Council. As a member of the deputation rightly stated, there was a reason why that representation should not be direct when the Medical Act was brought in, that is to say, that their being no Medical Register in existence at that date, it was therefore impossible to arrive at the opinion of the profession. Consequently, they must not imagine that if there had been in existence the means of making the votes of general practitioners available, direct representation would never have been brought forward and introduced into the Bill at all, constituting that Council. If he were asked whether he would choose to select a council, composed in its entirety of popular representatives sent by the general practitioners of the country and by the universities, by means of the general councils of those universities which have been recently enfranchised, more especially in Scotland, he would say no; because, however desirous he might be of popular representation, he was anxious that it should be limited in quantity, and that they should not be reduced, as was said in regard to the Reform Bill, to the dead level of Salisbury Plain. Neither would he elect to have a council wholly nominated by the Crown, nor to have an irresponsible council; he would select something between. The council he should prefer, if he had the means of carrying it out, would be the present council, which contains the University element, and the choice of members by the primates of the universities; secondly, the medical corporations and their election either by fellows, as in the case with his own corporation, and that of his friend Dr. Fleming, and others, or by the Council, as in the case of his friend Mr. Hawkins; and, thirdly, the Crown element; but, in addition to that, he would prefer members elected directly by the registered practitioners, in order to add to those other three elements, the popular element which he thought would tend—heterogeneous as those others certainly were—if joined together in a chemical union, to make a homogeneous and salutary compound. He advocated such a council on account of its variety. He thought it was of very great importance indeed, that they should get a variety of constituents, because he felt satisfied that by that principle of selection the different interests would balance one another, the Conservative proclivity of the one operating as a drag, perhaps, upon the radical tendencies of the other, and *vice versa*. He might be permitted, he said, by some of his numerous friends, with the inconsistency of holding very radical doctrines upon that matter, but at the same time a Tory in general politics.

The **President** trusted that his friend Dr. Andrew Wood, would not introduce general politics there.

Dr. **Andrew Wood** observed he used it as an illustration of his subject, and he would show them the analogy. It was that he thought that propounding so-called radical doctrine, he was advocating the most conservative course it was possible to adopt.

The **President** asked to be forgiven for reminding the learned doctor that that assembly did not argue questions there as to whether they were conservative or radical, but as to whether they would be for the good of the profession or not.

Dr. **Andrew Wood** said he could show them how it was he applied the illustration; he said it would be conservative of the Council to adopt that reform, and for that reason, and that alone, if the Council would not head the agitation which had been going on outside, he would stand by its present constitution, notwithstanding what they had heard that day in regard to agitation, which was sure to occur if they go to Parliament for a bill; in all probability in the reformed Parliament we might have, he said, the old constitution of Council *bouloersé*, and they might have perhaps those conservative elements which exist in it destroyed. He thought he was quite justified in using the argument to induce them to take such steps as would show that they are determined, having considered the subject most carefully, not to be prevented by obstacles in the way of introducing that popular element into their constitution, which might perhaps be the preservation of the Council. He thought it would tend to strengthen the hands of the Council, a thing they greatly needed; he was one of those who desired more than once to go to Parliament for the purpose of having additional powers conferred on them for enabling them to enforce their regulations; but he had no hope of success in that, unless they put the Council on a more popular footing. Another thing is that it would make the Council more popular out of door. For whatever the deputation might have said to them that day, that all they have done has been excellent, yet true it was, and a verity, that for the ten years that Council had been sitting, they had in some way or other—explain it how they might—not been so popular a body as hitherto. He also thought the infusion of the popular element, and the admission of members from different parts of the country, would rouse an interest in their deliberations, which was not at present felt by them; he had often been astonished on making allusions to the Medical Council, and to what it was doing, to see how little gentlemen in the provinces cared about it, and how little they knew about it. But if they were ever vested with the franchise, they would watch carefully to see how their representatives acted for that Council, and they would take an interest in their deliberations, which would give a force and influence to all which they hitherto had never enjoyed. He thought also it would have the effect of giving more certainty to the decisions of their Council, and driving away that debility—he did not mean it offensively—but he might almost say a vacillation which had generally characterised the decisions of their Council. It would also, he said, have the effect of producing among the professional gentlemen an *esprit de corps* which they had not then. That had been his experience in the case of the Scottish Universities. Before the passing of the recent act, the graduates attended their lectures, took their degrees, and there was an end of their connection with the universities, but he found at that moment that they were in the midst of elections which were exciting the greatest interest, both the election of our chancellor and in the election of members of Parliament, and the result was that there is amongst all the members of the universities an *esprit de corps* raised, which had attached them to the universities, and which he believed would greatly benefit those bodies.

At this point the President having to withdraw, Dr. SHARPEY took the chair.

Dr. ANDREW WOOD continued—Another reason why this reform should be carried out was, that the provincial element was not sufficiently represented at present. His scheme would be this, that the country should be divided into electoral districts. Taking the Medical Directory, he found there were 16,360 members of the profession: in England, 12,500 (comprising 2838 in London, and 9691 in the provinces), in Scotland, 1717, and in Ireland, 2139. He therefore suggested the advisability of increasing the numbers of the Council by six. He would add one member more to London, and by separating the districts, or rather the provinces, into three districts, Northern, Midland, and Southern, he would obtain manageable electoral bodies of about 3000 voters, and then England would be well represented. In regard to Scotland, with all his national love and desire to do what he could for her, he thought, in justice, she could not by any possibility claim more than one member, and the same with regard to Ireland. There were reasons for dividing England into districts, otherwise all the members might be chosen from London, and the provinces would yet go unrepresented, and he would not hesitate to say that the gentleman who would get returned for the provinces—able men, high in their profession, who were now practising there—would be cordially welcomed by the Council. Moreover, other advantages suggest themselves of dividing the districts, which would enable one to obtain manageable members for the position of scrutineers, &c., and the plan he thought of adopting, was that the registrar of the Branch Council of England should issue and receive the voting papers for London, and appoint a special registrar for each three of the English districts, one for Scotland and one for Ireland—to whom the voting papers would be returnable. Then the numbers would be summoned up by those registrars respectively, the presence of the mover and seconders of the candidates, and the result being ascertained, would be sent up to the President, whose duty it would be to notify the election in the *Gazette* to the country. He had given these particulars to show that the scheme he proposed was a practicable one; but, of course, he was anxious that the matter should be referred to a committee to consider the details. He was opposed to any curtailment of the members of the Council, in order to admit the popular representatives; because, who was to be disfranchised? He questioned if there were any Marcus Curtius ready to leap into the gulf for the sake of pure patriotism, and he believed, any attempt to modify the existing constitution in that way, would bring the whole house about their ears. It had been often said, and especially by the medical press, that there was a great deal too much talk in the Council and very little work. In fact, some of the journals had gone so far as to select the inveterate talkers, at the head of whom he believed Sir Dominic Corrigan enjoyed a proud pre-eminence; he (Dr. Andrew Wood) came second, and his friend, Dr. Alexander Wood, third. He did not care for that, for if they expected members to come here as simply delegates to carry measures without discussion, they had very much misapprehended their men. There was no deliberate assembly in the world where there was not a very great deal of superfluous chatter. Go to Parliament, and ask the reporters if it was all wheat and no chaff there, and they would soon tell you their knowledge of the affair. The truth was that just in proportion as views got ventilated in free discussion the consequences were good. He therefore maintained that a great many accusations had been brought against the Council with regard to talk, which were unfair, and if it were hinted that the admission of popular representatives would increase the talk, he answered that provincial members were, as a rule, common-sense men, whose opinions it would be most advantageous to the Council to hear, because they were constantly in direct contact with large numbers of their brethren in the profession and with the public, and therefore knew by experience what were the wants of the profession on the one hand, and the wants of the public on the other. Again, it was said that the Council was already too numerous. He did not think so; and if anyone had come into the Council-hall yesterday, and seen five or six committees, they would arrive at a very different conclusion. He was pleased to see a tendency, day by day, to increase working committees; and he believed that six more members upon the Council would be a great assistance in this respect, and that the deliberation of the Council would be shortened by having the work done to a great extent by committees. But the great master grievance was the expense, and he found that so distinguished a man as the Right Hon. Robert Lowe had taken occasion the other day to allude to this. He (Dr. Andrew Wood) had for some time past deplored this expense. Being subject to the reproach, whether justly or unjustly—he did not think justly—worked in a very baneful way against the influence of the Council, and therefore he would be the last to propose any addition to the numbers of the Council; he was ready to advocate a measure which would not increase but decrease the expense. By reducing the fees from five guineas a day to £4, and, still better, to £3 10s., there would be a diminution. But better than that, he was thoroughly convinced that it was the bounden duty of the Council, by a self-denying ordinance, to reduce their fees from five guineas down to two guineas. Was it an object of money to any of them? He did not believe that the men who composed the Council should be men who could be swayed by pecuniary motives; and if the remuneration were levelled to two Guardians, they would not only add to the expense of the Council, by the addition of the six members, but would save nearly £600 a-year. He was satisfied that just in proportion as they decreased the expenses, and took away that cause of opprobrium, the cause of the Council and its welfare out of doors would increase. It must be but an honorarium at the best—for he was satisfied that the majority of the gentlemen sitting round, were attending even now at a large pecuniary sacrifice; and he felt, therefore, that they ought not to be treated in the manner they had been in the medical journals, in reference to this matter. However, he would say, take away even the chances of such a reproach by adopting such a scheme as no one could cavil at. As a member of the executive committee, he had to come to London from time to time, and two guineas a-day were considered a sufficient remuneration for his services. Why should they make fish of the executive committee, and flesh of the General Council; let them embrace the low tariff and save £600 a-year, and he would be bound to say they would not feel the same difficulty that was felt with regard to the disestablishment of the Irish Church, for they understood well enough how to dispose of the money. It was said by this measure they would introduce the element of discord and agitation. He did not fear that—he never found when men were enfranchised that they were one iota deteriorated—he had been educated up to that point. He was certain a little wholesome movement in the profession would, upon the principle of *agitation purgate*, be of vast service. He tendered to the Council his best thanks for their patience in listening to his proposed plan of action. By voting for the present resolutions they would not pledge themselves to any one course, except a resolution containing the words—"with a view to determine whether it be advisable that it should be based on a more popular footing," could be said to pledge them. He was pleased to say Sir Dominic Corrigan agreed largely in the great features of the proposal, and had paid him the compliment to second the motion.

Sir D. J. **Corrigan**, in seconding the resolution, said he would reserve any observations he might make to a future period of the discussion.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 8, 1868.

THE CONSTITUTION OF THE MEDICAL COUNCIL.

The great question of the week has been the Reform of the Medical Council. Whatever else may remain doubtful in the conflict of opinions, it is now clear to all who do not refuse to see the signs of the times, that the constitution of this body is unsatisfactory to the bulk of the profession, and that its reform must be the one great object for which all true medical reformers must strive. The cry first efficiently put forward by men who had devoted much time and attention to medical politics, and taken up by the Medico-Political Association, and then by the British Medical Association, has found an echo within the Council itself. The result is that several plans are before the profession, and each of these deserves earnest consideration. They may all be arranged under one head—proposals for the registered practitioners of the kingdom to be represented in the Council which is supported by their contributions. These proposals take two forms—first, that of direct representation by increasing the number of the Councillors by men chosen by the profession; second, that of indirect representation, by allowing those who hold the diplomas of the Corporations to elect the representatives of those bodies. The British Medical Association adopts the first plan, and is supported in the Council to some extent by Dr. **Andrew Wood**. The champion of indirect representation is Dr. **Prosser James**, who has staked the support of his professional brethren in his contest for a seat in Parliament upon the plan of Medical Reform which he has sketched in his address to the electors of the Universities of Edinburgh and St. Andrews, already published in our columns—(**Medical Press and Circular**, June 24).

The Medico-Political Association in its programme only demands the representation of the profession in the Council, and we, therefore, presume that either plan may calculate on its support; though whether it would be satisfied with either alone, and if not, which it would desire first, does not appear.

Our readers will naturally anticipate some remarks upon the subject, and we are aware that the profession is so interested in the question, that we give a much fuller account of this debate than of the others which have occupied the Council.

We have more than once felt constrained to give expression to the fears that have been expressed in so many quarters about increasing the number of the Council. Not that we feel that increase of numbers must necessarily multiply bad speeches—it might even rather increase the proportion of good ones—but there are certain practical difficulties not easily overcome. For example, the question of expense, although magnanimously neutralised by Dr. **Andrew Wood**'s proposal, will remain so long as his proposition receives a cold reception. But there is a much greater difficulty than this, and one which was most aptly put by the President in his business-like, sensible, and straightforward reply to the deputation of the British Medical Association. He pointed out, most properly as we think, that the Council is not self-constituted, and can neither increase nor diminish its numbers without an Act of Parliament, and he stated, what is well-known to all acquainted with public affairs, that there is no hope of obtaining such an Act within any reasonable period. That is an objection to the proposal for direct representation which has never yet been answered. It applies equally to the proposal of the Association, and to that of Dr. **Andrew Wood**, and in fact, to every proposal to reform the Council that has been made, *except to that of* Dr. **Prosser James**, which, therefore, we may now consider.

This gentleman appears to have long-cherished the idea that the profession may be adequately represented without any legislative interference. In point of fact, the scheme he has just published was proposed some twelve years ago, before the Council came into being, and was at that date submitted to Lord Palmerston's Government. We think it is to be regretted that a scheme so long before the public, and which it would be so easy to carry out, should not have received further consideration by the Council, especially as parts of it were over and over again alluded to by various speakers, who seemed to lack the courage to explain it in all its details, or to advocate something proceeding from an outsider.

A few words would have given it in its simplicity. Dr. **Prosser James** proposes that the representative of each Corporation at the Council should no longer be appointed by the governing committee of the Corporation, but elected by those who hold its medical diploma. That, we believe, is the pith of his scheme, and that would unquestionably give representation to the profession. It would very possibly give a greater voice to the profession than the addition of the largest number that has been asked for by the advocates of direct representation.

Then, that this scheme is by far the most practicable, and most easily attainable, appears from even a cursory examination. For example, it does not require the intervention of Parliament. The Corporations themselves are capable of carrying it out, and if the Council should express its approval of the plan, we do not doubt that they would be willing to do so. Besides, we heard with great pleasure from Dr. **Paget**, that his constituents in full numbered 4500—that is, as he explained, every one of those graduates of the University could exercise the franchise *if they wished*, and although, practically, the matter is left in the hands of a small committee, the right still exists. Here is a brilliant example of liberal treatment set by the University of Cambridge, which other bodies would do well to imitate. If all thus freely accepted the plan of Dr. PROSSER JAMES, it is not improbable that there would be no further demand for a reform of the Medical Council. Will the Corporations take the hint, or will they stop the way until the profession outside is compelled to appeal to Parliament for itself?

Again, the scheme of Dr. PROSSER JAMES is more feasible than the other, inasmuch as it is not complicated with other subjects, on which differences of opinion are rife. It does not affect the numbers of the Council. It would not increase the numbers, and so would not play upon the fears of those numbers which have been so freely expressed. On the other hand it disfranchises none, and so excites no opposition on the part of condemned members.

Further, it does not touch the question of expense, concerning which there seems no chance of any two people coming to the same conclusion.

For these and other reasons we think this plan has the merit of being eminently practical. A resolution that such a procedure is just or desirable would, we anticipate, suffice to bring it into general operation, and this much can be effected without any preliminary difficulty, or any need to wait the pleasure of a minister or the decree of Parliament. The Council then might do well to consider the propriety of making itself the *bonâ fide* representative of the profession, in a manner thus simple and effective. The profession generally will think that such a resolution as this would have been worth more than all the talk that has been indulged in this session.

NOTES ON THE GREAT DEBATE IN THE MEDICAL COUNCIL.

THE constitution of the Medical Council has long been a subject of interest, and it is capable of being looked at from so many points of view that a few stray but disconnected notes on the late debate may not be uninteresting.

GENERAL PRACTITIONERS.

Dr. Andrew Wood, in the course of his speech, said eight members were already general practitioners. He was, however, corrected as to this, more than one explaining that he could lay no claim to the term. It is certainly of little consequence what department a man practises, and if the popular element, as it was more than once called, be introduced, there will not necessarily be more general practitioners. If any new persons send new representatives, it will be *registered* practitioners, and the terms are not synonomous.

DR. ANDREW WOOD'S PLAN.

The scheme submitted by this gentleman will be seen from our report, possesses many points of superiority to that of the association. It is more definite, more complete, more practical. He would add six members (four for England, one for Ireland, and one for Scotland) to be elected by *registered* practitioners. Ireland, he calculated, contained 2139 registered practitioners, Scotland 1717, England 12,500. He would divide England into districts, and give London one member, Northern, Midland, and Southern districts one each. No constituency would exceed 3000, which is about the number for London.

How great a dread is entertained by many of popular elections is shown by a remark of Sir B. Brodie's, quoted in the debate, to the effect that "popular representation was the very worst calamity that could happen to the profession." We presume few people will endorse the opinion of the late baronet on this point.

TORIES AND RADICALS.

The introduction of the terms common in general politics excited both amusement and surprise. The President said that the Council did not argue questions as to whether they were Conservative or Liberal, but good for the profession, and asked speakers not to introduce general politics. He did this firmly and well, and indeed throughout the session performed his duty in a manner that gave general satisfaction.

TRADING IN DIPLOMAS.

In repartee, when interrupted, Sir D. Corrigan again called attention to the monstrous fact that one body had in one year taken £10,000 for diplomas given without examination.

This was hard on the Northern College, which only erred in amount, for did not the college in whose hall he spoke do the same in a smaller way—nay, did it not set the example of a year of (dis)-grace?

TAXES OR FEES.

Dr. Paget very ably argued that the registration fee was not a tax, and that to call it so was a misapplication of terms. Moreover, he thought the Council did not govern the registered practitioner. No one pointed out to him that whatever may be the correct term, the money which supports the Council comes from the profession, and they who pay at present get nothing for their money but the right to have their names on the official directory. Dr. Paget admitted that if representation were, as he thought not, a right by virtue of the tax or fee, it may be expedient to grant it. His speech was one of the best we have heard in the Council.

INDIRECT REPRESENTATION.

Several speakers alluded to the possibility of granting *indirect* representation, by popularizing the mode of election of the representatives of the corporations. This is the plan originated by Dr. Prosser James, and so fully explained lately by him. It evidently commended itself to many who could not tolerate the notion of direct representation. Dr. Paget said the whole Cambridge University constituency had a right to vote for him, and he recommended Sir D. Corrigan and Dr. Andrew Wood, who so ably advocated popular representation, to try and carry out their views in the bodies that sent them. He thought about twenty men elected Sir D. Corrigan, and that the graduates of the Queen's University might fairly ask for a vote. The Fellows of the College who sent Dr. Andrew Wood, should be persuaded by that gentleman to give a vote to their licentiates. Dr. Paget's speech made a sensation in the Council, which will be produced out of doors. The facts and arguments will go far to establish the justice of all that Dr. Prosser James has brought before the profession. Several other members incidentally alluded to the plan, but none spoke out so clearly and with such manifest approval.

THE UNKNOWN FUTURE.

Dr. Stokes pleaded that all the machinery of legislation takes up much time, and that the Council was a new body; and more could not be expected of it. He dreaded the introduction of questions they could not decide if popular measures were adopted. Such questions as remuneration of medical men, or of witnesses, coroners' fees, and above all, private professional differences, might be dragged in by members elected by the profession. Why not? The Council is *paid*, and might very well direct its highly developed talking capacity to subjects that would interest those who pay.

GREEK.

A considerable portion of Saturday afternoon was occupied with a lively discussion as to whether Greek should be transferred to the compulsory subjects of preliminary education. Each speaker seemed satisfied that he alone comprehended the Alpha and Omega of the question, so that the debate was more amusing than might have been expected.

We the less regret that we have not space for a full report of this vivacious discussion, as our readers, like the few listeners present, would probably pronounce it "all Greek" to them.

As the language is so familiar to the Councillors, and some confessed to reading it for pleasure, we beg to suggest that in future the proceedings should be conducted in Greek, when it is probable that the Council would at least be a little less loquacious.

Notes on Current Topics.

Medical Statistics of the Abyssinian Expedition.

We are enabled to publish the following authentic information of the health of our troops, and the mortality in the recent campaign:—

Average daily sick to numerical strength, 5·8 per cent; average of deaths to numerical strength, 1·3 per cent.; mortality of officers, 11 per cent.; of men who died in the high lands, 17 per cent.; of men who died on the coast and in hospital ships, 20 per cent. Three medical officers died, one of whom was on his way to Magdala; and three officers met with violent deaths, of whom one committed suicide.

The above figures speak eloquently of the perfection of the sanitary arrangements, and of the activity and intelligence of those in charge of the department. Perhaps no expedition attended with similar difficulties was ever carried to so complete a success with such insignificant loss of life, or so few men put *hors de combat*.

The Future President of the Medical Council.

The approaching expiration of the term of office of Dr. Burrows, who has so ably and so impartially carried out the arduous duties pertaining to this important post during the last five years, has caused a good deal of speculation as to his probable successor.

We hear that, as it would cost some £300 to summon the Council for the mere purpose of electing a president before the session of 1869—as was the case on the decease of the gentleman who, prior to the appointment of Dr. Burrows, occupied the presidential chair, the Council were resolved to proceed with the election during their present sitting. To show the appreciation of the manner their retiring president has conducted the business of the Council, the members unanimously requested him to allow himself to be re-elected unconditionally. It is therefore within the province of Dr. Burrows to fill the office for one year, or for the full term of five years. This decision must be very gratifying to Dr. Burrows; but we are credibly informed that he will not fill the post after the expiration of the session 1869.

The Royal College of Physicians of London.

The nomination list of the College has at last appeared. A glance realizes our predictions, and shows us how utterly hopeless it is to look for better things under the present system. The few recent good and able men elected on the Council, who would do justice, are out-voted and unable to snap the "red tape," rotten as it is. But how could a more just selection of members for the Fellowship possibly be made from a body which, as a rule, is carefully recruited from the same unaltered source? (the system being, that the members of a clique elect their own successors, who, there is little doubt, owe their selection to unanimity of views, plans, and objects of their predecessors). *The only chance of reform in the acts of the Council, must come from a reformed election of the Council itself.* This change may not occur in this year, still, little union as there is in the medical profession, and much as the very nature of the profession itself tends to isolate its members, we cannot think so meanly of the majority of such highly educated men as to believe that when once awakened to the absurdity of such a clique, dealing out (what ought to be a well-won and honourably worn distinction), if not in a direct spirit of favouritism, at least, on no comprehensible principle, and subject to no control from the independent body of the Fellows. Since the historic days of *tyranny*, none has been so intolerable as that of an *oligarchy*, and for the plain reason that it rules through the passions, prejudices, and petty malice, not of one, but of many minds. The worst of tyrants has moods in which justice claims some share, but in the tyranny of a clique there is always some member who has either a point to carry, a spite to gratify, if not an actual injustice to commit.

The ultimate tendency of such a *rule* must be to sink all the dignity of the College, to degrade the scientific character of the Fellowship, and to alienate the respect and loyalty of all its members.

Royal College of Surgeons of England.

The contest for election into the Council, which has been more earnestly contested than usual, terminated last Thursday.

As we have previously explained, there were four vacancies, one occasioned by the decease of Sir William Lawrence, Bart., one by the resignation of Mr. Hodgson, and the other two, the retirement in the prescribed order of Professor Partridge and Sir William Fergusson, Bart.; these two gentlemen offered themselves for re-election. The other candidates were Mr. Erasmus Wilson, F.R.S.; Mr. John Gay, Surgeon to the Great Northern Hospital; Mr. G. L. Cooper; Mr. C. Brooke, F.R.S., Surgeon to the Westminster Hospital; Mr. J. Simon, F.R.S., of the Privy Council-office; Professor Humphry, F.R.S., of Cambridge; and Mr. Luther Holden, Surgeon to St. Bartholomew's Hospital. The election, which was by ballot, commenced at two o'clock, and was not brought to a close until six o'clock, when the President, Mr. Hilton, declared that the choice of the Fellows had fallen on Sir William Fergusson, Bart., Mr. Simon, Professor Humphry, and Mr. Holden. The numbers polled by each candidate were as follows: Fergusson, 206; Simon, 157; Humphry, 148; Holden, 136; Gay, 120; Wilson, 108; Partridge, 103; Cooper, 58; and Brooke, 32.

We congratulate the successful candidates on their election, and call on them to show their regard for the profession, by supporting a liberal policy.

Medical Parliamentary Representation.

An *on dit* is current in Dublin, that at the approaching general election, Sir Dominic Corrigan, Physician to Her Majesty the Queen in Ireland, will offer himself to the electors. It is almost superfluous to say that Sir Dominic Corrigan's success would be a source of the greatest satisfaction to the entire profession in Ireland. We cannot, however, think that the candidature of the learned baronet is likely to be pressed, as the electors of the Borough, County, and University of Dublin, have very decided Conservative leanings.

First-Fruits of Sanitary Reform in Liverpool.

There were registered in this town during the last six months 6952 deaths. This is 1640 less than the average of the last ten years. Of the total deaths, 48 per cent. were those of children under five years of age.

What should we Drink?

Under this title has appeared, from the pen of Mr. Denman, the author of "The Vine and its Culture," a very smart criticism on Mr. Beckwith's report, and one that will be read with great relish. We call attention to it, because we have fully appreciated its full flavoured sarcasms, and the great amount of information it contains. We are about to resume our reports on wine, as soon as the Medical Council report is complete, and shall perhaps again have occasion to refer to the opinions of both Mr. Beckwith and Mr. Denman.

Poor-law Salaries in England.

The profession, and notably the Poor-law Medical Officers of England, ought to feel shame that we should have to make public the following statement made recently at a public meeting by Dr. J. C. Reid :—

"The guardians in the north reckon their medical officer's salary as so much 'found money' to him. It is not in London only that whole streets spring up as if by magic; for in my district where there were only 100 inhabitants in North Seaton township sixteen years ago, there is now one of the largest collieries in the kingdom, containing a population of about 2000; besides the increase of streets, terraces, &c., in the sea-bathing town of Newbiggin itself, which must have doubled its inhabitants during the same period. Well then, with such an increase, I felt justified in asking the guardians to give me £20 a-year instead of £10. Save the mark! More especially as much younger men than myself, with no increase of population, had the salaries for their districts doubled, and in some places tripled; and the clerk to the board had a handsome addition made to his. But no, £20 a-year was far too much! Try £15. 'Tell it not in Gath, publish it not in Askelon.' The handsome remuneration of £15 per annum was rejected by a majority of three! Ten pounds a-year was deemed sufficient for attending the poor of eight townships, some three, four, five, and six miles from my residence, and providing medicines to boot! Mr. Chairman, I blush for the cloth when I tell you that a rev. honourable led the van of the opposition; and whilst I can count mine by thousands, he only can reckon his few sheep by hundreds. And whilst he annually receives his £1000 and odd hundreds, he thought me fully remunerated by a less sum yearly than he would purchase a dog for."

We repeat advisedly that the profession divides the ignominy of these accusations with the Guardians, for its members are responsible for having made such a state of things possible. If there existed in our profession a proper *esprit de corps*, a legitimate trade's unionism, if the public wish to call it so, such as protects the members of the legal profession from the undercutting system, it would be useless for Guardians, who now unhesitatingly avail themselves of our disunion, to offer such remuneration. Each and every member of Dr. Reid's board must of course be well aware that their salary did not even approach to paying the expenses of the office, but they also knew that if Dr. Reid objected to accept £10, or half that sum, candidates would be found good enough for paupers, if not [illegible] qualification, who would take the post at [illegible] perhaps at nothing at all but the hope [illegible] of stepping in front of a professional rival. In no other profession but ours is the underselling system allowed to exist, and we see no remedy for it but the same as is applied elsewhere, a penitential "Coventry" for every man who takes the bread from his brother's mouth, and degrades his profession by playing into the hands of unscrupulous Guardians.

We are happy to supplement our remarks on the drainage of seaside towns, by stating that the works undertaken and finished for St. Leonard's, have been in working order for several months, and continue to give the utmost satisfaction; whilst those of the neighbouring town of Hastings, necessarily on a more gigantic scale—are nearly completed, everything promising the most successful issue.

The decease of Dr. Kennion, F.R.C.P., of Harrogate, is announced.

◆

GENERAL MEDICAL COUNCIL PROCEEDINGS.

(Continued from page 34.)

Dr. **Rumsey** wished to correct one or two remarks in Sir Andrew Wood's speech. With regard to Crown nominees, he begged at once to say he did not think they were appointed to represent the interests of general practitioners. He had accepted his appointment on purely public grounds—for the protection and ultimate safety of the great community of this country, in matters of health and prolongation of life. He deprecated the thought of sitting on that Board as the representative of any single interest, except the interest of the nation at large. Again, Dr. Wood had said, Sir Charles Hastings, Mr. Teal, and himself (Dr. Rumsey) were general practitioners. Sir Charles Hastings was a pure physician; Mr. Teal, that great man had been called to rest since their last session, from the toils and cares of an honourable and laborious life, he was a pure surgeon; and with regard to himself, it was many years since he was a member of that body—the general practitioners of this country; and he stood there either in the capacity of surgeon or physician. Upon the general question much respect was due to representations of great associations whose deputation they had just received. He yet agreed to a great extent in their views, and with what had dropped from Dr. Andrew Wood, but still wished the Council to bear in mind that just in proportion as the representative element was strengthened in the Council, the less readily would Parliament consent to commit to them those administrative and executive powers, which many considered should be extended, so that, in fact, by increasing them in one way they would be weakened in another.

Sir **Dominic Corrigan** drew attention to an observation which had been uttered in the debate, namely, general practitioner. The memorial referred to "Registered Practitioners" of the United Kingdom, and it was obvious the distinction should be made and supported; because the representation of general practitioners, as a body, would be attended with insuperable objections. He was sorry the President was not there, because he felt compelled to question the course which had been taken in the conference with the deputation. He had challenged them to show that the Council had ever omitted to guard the interests of the profession, the conclusion being that if they had so failed, there was no necessity for any application. He recollected a time when the monetary affairs of a vast body were at issue, and a motion was proposed to have the financial matters put in better order than before. An official of the company, instead of listening to a discussion on the merits of the scheme suggested, jumped up and challenged any person round the table to declare in what respect he had been guilty of defalcation. He did not regard it as fair for the President to treat with the deputation, and but for the tact of Dr. Sibson there might have sprung up an angry wrangle on it. As regards the general question, he thought the arguments might be considerably narrowed, for he thought the Council should not enter on the consideration of any details by which the measure should be carried out. The only topic to which he referred, would be whether the principle was right or wrong, because if the principle was right then leave the details to a committee, and if wrong there would be no necessity to discuss details which would never be demanded to be put into operation; was the present constitution of Council then satisfactory to the profession in the United Kingdom, amounting to nearly 15,000 people? He considered, after the evidence they had, and after the arguments they had seen in the medical periodicals for a long time, it was nearly impossible for any one to declare the present constitution was satisfactory to a very large portion of the profession in the kingdom. It was not necessary to discuss the question raised by the president, that there was no chance of carrying a bill this session or next, for that was not the question. He had heard it said it was not necessary to add to the Council; that its duties being confined simply to registration and education, the representatives of corporations and universities, and of the Crown, were quite competent to deal with those subjects. But could they confine themselves to those two matters, or had they done so? Looking back at the journals in a cursory manner, he found that as long ago as 1860 they had considered the regulations of the Poor-law Board, and others, with regard to apothecaries' licences in England. Could any one say that was a question either of registration or education? Again, the question of inquests had been brought before them in the same year, and was it not obvious that they would have their knowledge and experience vastly increased upon such a question of state medicine by having among them men from different parts of England, Ireland, and Scotland. He (Sir D. Corrigan) confessed that he had no practical knowledge whatever of inquests, and if he had to consider the subject on a committee or elsewhere, he would be obliged to turn to these gentlemen whose absence from the Council he now regretted. Again, on the subject of vaccination—was there one member of the Council practically acquainted with it, or who had spent days and days vaccinating children and a register—not one. There, again, the importance of having popular representatives would be seen. Again, upon the question of medical witnesses—what experience had they upon the subject? He found in 1863 they had a very lengthened and able report on the Pharmacy Bill then introduced into the House of Commons. Was there any one in that Council, with the exception of Dr. Leet, who possessed any practical knowledge on that subject? The Weights and Measures Bill was another instance in which they could arrive at no satisfactory conclusion without the experience of these men; and even upon the question Mr. Syme so ably brought before them as to the best mode of education—whether young men should go for the first two years to a general practitioner, or the registered, or the surgeon of a county infirmary, and so on, or serve an apprenticeship. Upon all these matters the information which men who had acquired a knowledge of their profession by going into the world, and mixing in it, and practising, was required, and who knew what their own defects were when they went out into the world, could give, would be most available to the Council, and was not possessed by those members who at present constituted it. Within the last two or three days they had had a most important subject before them—namely, the lunacy laws. Could there be a subject upon which they must more regret the absence of those men than that? For one case of lunacy which came before men in their position, five, ten, fifty, and one hundred would probably come before the general practitioner. Dr. Sibson had also put forward as a reason for advocating the step which he proposed one of the most important principles recognised everywhere in this constitution—namely, that there should be no taxation without representation, and there was no anomaly, as far as he knew, in England, of a representative body paid for by funds derived from the taxpayers in which the taxpayers themselves had no single vote in the appointment of the representatives. He believed that any Medical Act Amendment Bill in which there was not a clause for the representation of the men who were taxed to pay the Medical Council, would never be listened to by the House of Commons. He also agreed that such a measure would popularize the Council, for disguise it as they might, they were looked upon at the present moment by the bulk of the profession as a Corporation that had done very little hitherto to protect the interests of the professsion, and one with which the profession had no sympathy. Upon the subject of education, in which they all expressed so deep an interest, he did not think there was any body of men in the United Kingdom who had so strong an interest in maintaining a high standard as the registration practitioners, while on the other hand the interests of the corporation was to get in as great a number as they could, so as to obtain as much money as they possibly could. I do not say their motive is that, but I say it is their interest. Had not they had a licensing body within their regulation which made £1000 in one year, by giving its qualifications without any examination, and was he to be "Oh, oh'd" at because he told the truth. He did not except the corporation which he himself represented. The College which had done him the honour of electing him president, was afraid to advance much upon the subject of education, because licensing bodies, with equal privileges, had not gone as far. The men who represented the profession at large, would have a strong interest in supporting nearly the whole of this Council (because the representatives had very different feelings upon the subject from those whom they represented) in raising the standard of education, because they would have very possibly a direct interest to increase their own respectability by taking care that no man entering the profession with a low *status* either as to education or character. Lastly, the Council would be able to command more respect from the Government of the country. It was no use disguising the fact that when once men obtained their degrees, every connection with the University was severed. But once let them have a representation upon this Council, and a great accession of strength would be the result.

Dr. Alexander Wood then moved the following amendment—"That the Council, as a committee of the whole Council, take into consideration its present constitution, with the view of determining whether any alteration should be made in its constitution in any future Medical Act to be proposed."

Mr. Hargrave seconded the amendment. With regard to the question which had been asked, what good had the Council done? he would give them one great fact amongst others—it had brought the profession of the three kingdoms into union, and if it had done nothing else but that and prepared the Pharmacopœia, it need not be ashamed of its labours.

Mr. Cooper supported the amendment.

Dr. A. Smith preferred the amendment of the two, as the amendment did not bind the Council to adopt any particular course.

Dr. Paget said he should not like to give a silent vote upon this occasion. He had listened with very great interest to the discussion because he had been anxious to hear what would be said in favour of the resolution, particularly as it came recommended by an association to which he felt somewhat attached, and to which he had the honour of being elected President only a few years ago: an associotion which he believed was doing a great deal of good by its gatherings and local meetings. Some reasons in favour of the course proposed had certainly been heard, but he confessed that in his mind they had not preponderated over the objections which he saw to the scheme. Before entering into them, however, he wished to join Mr. Hargrave in rejecting the view which Sir D. Corrigan took of the course taken by the President, and he did so, especially, as Dr. Burrows was not present to defend himself. He thought the questions put by the President were perfectly fair, and not only so but necessary. The very fact of a deputation coming to the Council, and requesting it to take into consideration, and actually to take part in steps towards the alteration of its constitution, implied *prima facie* dissatisfaction with the acts of the Council, and that was abundant justification for putting the question whether there was any charge to be brought against the Council. Moreover, the resolutions which were read implied the same thing in another way. One of them was—"That we are of opinion that if the Council, in consequence of the addition of the members to be elected by the profession, should deem it advisable to recommend the diminution in the number of representatives of the corporations, a corresponding reduction may then be made in the representatives of the profession. What was that but a tolerably plain indication of an opinion that the proceedings of this Council were rather adverse as it was at present constituted to the interests of the profession. Or else, why should a bargain be proposed, that in proportion as the numbers of one part of the Council were reduced, the numbers of another part should also be reduced? The question put by the President was therefore not only fair, but necessary. There was one argument which if he were to admit it, would at once convince him that what was proposed ought to be done, and that was the question of right. That was put by one of the speakers of the deputation, and repeated by Sir D. Corrigan—"no taxation without representation." No doubt there was a just and proper connection between those two things which was always recognised in the constitution of the country, and properly recognised; but they must not be misled by mere words, they must consider what the principle involved in that phrase was. It was this, that those who are liable to be taxed ought to be represented in the body that taxes them. But how did that bear upon the present question? To whom were they proposing to give a voice in this Council? To the registered medical practitioners. Well, had the Council any power to tax them? (Dr. Andrew Wood, Yes.) None whatever, except in the instance of a gentleman who, for 5s., wishes to add an additional qualification to his name. He repeated, the Council had no power whatever to tax the registered medical practitioner. It was quite true that the fee of £2 or £5, as the case might be, was paid by gentlemen when they entered upon the profession, and wished to put their names upon the register, but it was not proposed that those gentlemen should be represented in the Medical Council, they were either medical students, or those gentlemen who had hitherto abstained from registering. But the representation was proposed to be put into the hands of those who had always registered, and those the Council had no power of taxing. It was, in fact, a misuse altogether of the term to speak of this fee as a tax. Every one knew the effect of increasing or reducing a tax; they felt it when the income tax was reduced or increased so much in the pound. Apply that test to the registered practitioners. Suppose registered practitioners were reduced from £5 to £1, would the registered practitioners be a bit the better off? Or take the reverse, and suppose the fees were increased from £5 to £50 (Dr. Andrew Wood, you cannot). Suppose it were, by way of illustrating the case, would any of the registered practitioners be a bit worse off for that? On the contrary, the only effect would be to check the ingress of new members into the profession, and the registered practitioners, as far as they would be affected at all, would be better off with an increased tax than without. Therefore it was really a misuse of terms to call the fee a tax at all, it was a mere entrance fee; the same sort of thing as was paid by a man when he graduated, or took out a diploma from the universities, or from one of the medical colleges.

The hour of six having arrived, the debate was adjourned till to-morrow.

WEDNESDAY, JULY 1.

ADJOURNED DEBATE ON THE REPRESENTATION OF THE GENERAL PRACTITIONERS IN THE COUNCIL.

Dr. **PAGET**, in resuming his speech against the motion, said it was represented that, because the Council was the governing body of the profession, therefore there was a right on the part of the governed to be represented upon it. He felt he ought to apologise to the Council for taking up its time in refuting that argument. But, as it had been repeated again and again, until he had no doubt it was accepted generally by the medical profession, it was necessary to say a few words on the subject. Everyone in that room was aware that there was no truth in the statement. He would test it in this way. If anyone of the registered members of the profession were asked individually, whether since the time the Council was established it had in any way governed him since his registration, he would speedily answer in the negative. Looking at the Medical Act, and reading it through, in what way did it confer any power of governing the registered members of the Council? There was only one single instance—happily a very rare one, in which the Council had direct power of interfering with members of the profession, and that was when a registered member had been guilty of infamous conduct in a professional sense. Not only were those cases extremely rare —only happening about once a-year—but even in them the Council did not act in a governing, but in a judicial capacity. By clauses 18, 20, 21, and 22 of the Medical Act, powers were given to the Council. What were those powers, and over whom were they exercised? They were to inquire into the proceedings of the different universities and other licensing bodies what their course of studies was for medical degrees; what their modes were of medical examination, and to test those examinations by visitation. The Council had also powers through the medium of the Privy Council of depriving those universities and licensing bodies of the right of granting degrees and diplomas. Those were the parties governed by the Council. Therefore, it was according to the very principle which had been quoted by the supporters of this proposition that those were the parties who had been represented on the Council, and must be represented if the Council was expected to work as well as it had been done hitherto. The talk upon the subject as to its being a question of right, therefore must be given up. But there was another view of the subject. Without there being any right in the matter, it might be advisable that the general profession should have direct representation on the Council. But then it was incumbent on the advocates of the measure to prove that the addition of such members would increase the power of the Council for doing good, and would enable it to perform better than it had hitherto done the duties imposed upon it. The *onus* of proof is on the advocates of the measure, and he confessed he had heard nothing like a satisfactory case made out. He did not see that the mode of election of those members would provide the Council with more efficient members than it already possessed. It did so happen that the members of the Council were composed of professors and officials of the different universities and medical corporations, and there were no medical practitioners in the Council then there could be a strong argument in favour of the present scheme, but, as a matter of fact, the great majority of the Council were practitioners, and it was a matter of almost certainty that their successors would continue to be so. He could, therefore, see no reason why the present members of the Council should not be just as good judges of matters which would come before them, as if they were elected by the profession at large. Sir Dominic Corrigan had quoted instances in which the questions brought before the Council were not purely questions of education. No doubt those instances had some weight as far as they went; but how far did they go, and what a very small proportion they bore to the amount of discussions and labour bestowed upon the subject of medical education? He could state, that since he had been a member of the Council, he did not remember a single question that had been brought before it, in which there had not been an abundance of medical information afforded by the members of the Council. Dr. Andrew Wood had stated very fairly and truly, what was entitled to some weight, namely, that the election of members in the way proposed would increase the interest of the profession generally in the Council. That was true *quantum valeat*. He also said that the members so elected would be better acquainted with the feelings of the profession generally. He (Dr. Paget) did not think so—he doubted it very much. He would take this as a test, supposing the alteration to be made. In the natural course of things the very gentlemen now appeared before them yesterday as a deputation would be many of them, the majority of them probably, returned as representatives of the registered members of the profession, who, taking the recommendations of those gentlemen (and they were as fairly open to criticism as the proceedings of the Council) he did not think that they by any means indicated a very near acquaintance with the feelings of the profession. He would take one of them as an instance. He found them stating this—"The sub-committee entertain no doubt that the profession will willingly pay the additional cost of their own representatives." Now, as we must all know, amongst the 20,000 registered practitioners, there was not one in a thousand that entertained the same opinion as those gentlemen forming the sub-committee—namely, that the profession would willingly pay the additional cost of their own representatives. Therefore he thought it was at least open to doubt whether those gentlemen, eminent as they were, really represented the feelings of the profession generally, better than the members of the Council now sitting round the table. Again, it was actually said yesterday by the advocates of this matter, that it would strengthen the hands of the Council and increase its influence with the Government and the public. He cordially agreed with what Mr. Rumsey had said upon that point. He thought it was about the greatest mistake possible to think that the addition of those members would increase the influence of this Council with the Government and the public. Suppose the Council were very anxious to mend clause 40 of the Medical Act, so as to gain increased power of putting down the most notorious quacks, was it to be supposed that when deputations from the Council to the minister were to tell him their anxiety about the matter, that that deputation would be listened to more readily, or its recommendations more readily attended to, if they said we speak the voice of the profession? He (Dr. Paget) thought quite the the contrary; the influence of the Council with the Government and the public would be lessened by it being known or supposed that they represented the mass of the profession. He had read a communication which had appeared in one of the medical papers, from a gentleman who had expressed his views so admirably, that he would read his letter, as part of the observations he wished to make. The gentleman's name was Bewley, and he dated from Clara, King's County Ireland. He appeared to be favourable to the proposal now before the Coun cil, but he said—"The Council was never designed by the legislature to represent the interests of the profession. It was formed for the promotion of the interests of the public, and it is my belief the legislature never cared, or will care, one straw for the private or personal interests of the medical profession, or any other profession as such. In the eye of the legislature, the Medical Council, as well as all the other licensing medical institutions, except only for one object, namely—the good of the public." At the close of his letter, he gave the Council a little advice. He said—"If we are wise, we shall keep our individual interests in the background, and endeavour to prove, through the medium of the Council, the Medical Association, and the Press, that it is for the interests of the public, that every physician or surgeon shall be an educated gentleman." If he (Dr. Paget) could express his sentiments so well as they had been expressed in that letter he would not have borrowed it, but it seemed to him to be the shrewd, good sense of the matter. There was one objection to the proposed scheme which he thought should have been attempted to be met in some way by the advocates of the measure, namely, that the addition of members would increase the amount of talk. Dr. Andrew Wood attempted to meet it in this way, but I simply assert that the addition of six members would decrease the amount of talk. Now, with the greatest possible respect for Dr. Andrew Wood's opinion in this particular instance, he would have liked to have seen it supported by argument. It seemed to him as a matter of arithmetic that the addition of six members would add to the talk by exactly one-fourth; and, indeed, if those gentlemen were expected to advocate the interests of their electors (and that was one of the grounds upon which the proposal was based), they must make speeches in order that they might be read, and his opinion was that they would add considerably more than one-fourth to the talk. In fact, that was one of the chief objections, and it was not to be met by what was really nothing more than an expression of opinion the other way. Again, with regard to proportionate representation, the proposal of the deputation yesterday was such that the vote of one gentleman north of the Tweed would go further than that of three south of the Tweed, the practitioners in England and Wales being more than six times more numerous than in Scotland. He was quite satisfied with the constitution of the Council as it was, and he thought that Mr. Hargrave hit a good point yesterday when he said, what a good thing it was that by means of the Medical Council, the medical men of the three kingdoms had been brought together, and had come to a common understanding upon so many subjects. He quite agreed with that, and he was prepared to maintain that the Medical Act had done for medicine what legislation in the Houses of Lords and Commons had never been able to accomplish for the other learned professions. Not to refer to religious questions—look at the profession of the law. Englishmen could scarcely understand Scotch terms of law, and he supposed there would be quite an outcry in Scotland if it were proposed to adopt the term "endowment', instead of "mortification." Or if it were proposed to assimilate the law of marriage in Scotland to that of other countries, he would be quite prepared for a rebellion. (Hear, hear, from Dr. Alexander Wood.) But on the subject of medicine, the Medical Act had brought about a complete union between the countries. Again, the method of election which was proposed would not be so simple as seemed to be imagined. He (Dr. Paget) represented an university where the elections were conducted by voting-papers, and it had taken the recognised official, with the assistance of three assessors, sitting three or four days, and working hard, in order to get through the labour. The number of votes given was 3334, and he ventured to say that if all the votes had been given by voting-papers, as proposed by this scheme, it would have taken more than four days—and very hard work it was. The legitimate expenses of advertising, &c., to which the two members had been put amounted to above £2000 at the last election, and it was not by any means a strong contest, both gentlemen being of the same politics. But the proposers of this had no notion of what they were putting upon the registrar, or of the questions that would arise in cases where there was a close contest. This question was not one of sentiment, but what they had to consider was whether it was good and ought to be followed. He felt bound to give a little advice to the proposer and seconder of the resolution, and hoped they would take it in a friendly way. The body that returned Sir Dominic Corrigan was a very popular body. All the old Universities of England [illegible] bodies. The [illegible] that returned him (Dr. [illegible] larger than [illegible] body, having more [illegible] than any of the electoral districts proposed by Dr. Andrew Wood—it numbered 5400 voters. He would suggest to Sir D. Corrigan, who was elected by a most distinguished body of twenty gentlemen—the council or senate of the university—that the Queen's University in Ireland had, like the University of Cambridge, a number of graduates. At Cambridge the franchise was restricted to Doctors and Masters of Arts, and supposing the Doctors and Masters of Arts of the Queen's University of Ireland were to be privileged to elect their representatives to the council, that would be a good beginning of public representation, and might be carried out without any difficulty. Again, he would give the same advice to Dr. Andrew Wood, with regard to the body he represented, and he gave that advice the more readily, because he was sure the choice of those bodies, upon the basis of a wider constituency, would still fall upon the same gentlemen to represent them.

The debate was continued by Drs. Sharpey, Stokes, Storrar, and Risdon Bennett, who opposed the motion, and endorsed the views of Dr. Paget.

Dr. **Parkes** spoke in favour of the motion.

Dr. **Alexander Wood** expressed a wish to withdraw his amendment, stating, at the same time, his entire opposition to the motion; and

Professor **Syme** moved the following amendment:—"That under present circumstances it would not be expedient for the Council to consider the propriety of attempting to obtain a change of constitution."

Mr. **Cæsar Hawkins** seconded the amendment.

Dr. **Acland** would vote with some reluctance against the motion, for he would much have preferred moving "the previous question," if that course were open to him. He believed the proposition was most unfortunate and inopportune, and regretted extremely it should have been brought before the Council at the present juncture, when so many important practical measures were under deliberation.

The **President** said it was necessary to consider that the deputation which had been received professed to be a deputation from the committee of the Council of the British Medical Association, which title seemed to him to diminish the force of the memorial, but he wished to know whether the memorial was to carry with it the force of the great association itself, or whether it was merely a memorial coming from an active committee of that association, to ascertain which he had put those somewhat searching questions. They would see by the wording of the memorial, "The deputation from the British Medical Association beg to submit to the consideration of the General Medical Council the following propositions founded on resolutions passed at the annual meeting." So that it was not with the resolutions passed then, but propositions founded upon them, with which the Council had to deal. Resolutions, it was well known, might be passed at a general meeting, but upon being put into the hands of a committee, propositions might come out of those resolutions which were really not exactly the precise opinions of the body which had sent the resolutions to the committee, and, therefore, he wanted to know distinctly whether those propositions really had the sanction of the whole body or not. He did not suppose for a moment there was any attempt to deceive the Council, but he thought it doubtful whether the propositions had been proposed separately to the meeting at large. If they had been, they would have great force; but if not, that force would be diminished. He made that explanation, not for his own sake, but to those members of the Council who were not quite satisfied with the course he had pursued with respect to the question upon the motion of Dr. Andrew Wood, seconded by Sir Dominic Corrigan; he had before him a printed copy of the speech of Dr. Paget, and, he would say, I beg you to accept it as my speech, in the same way as Dr. Paget himself has read those admirable observations from a practitioner in Ireland. There was no doubt the Council did represent the interests of the profession in matters over which it had control, and it ought to represent the interests of the public as well; if the Council did not represent the interests of the public as well as those of the profession, he did not believe it would have anything like the influence or authority that it has. As Dr. Storrar had well pointed out, the Council was an administrative body to carry out an Act of Parliament. If it were a council to [illegible] all the interests of the profession, its material and [illegible] and those other social questions which had [illegible] forcibly and ably by Dr. Stokes, then he [illegible] the Council did not at present repesent the medica[illegible] and that some such change, as had been proposed, would [illegible] proper and right. But the Council did not attempt to represent such interests, and having in view its proper duties, if those suggestions were carried out he could not say that the Council would be improved. They must all bear in mind that the Council had limited objects in view, and they were quite aware that there were many men in the profession who did not find the routine of the profession sufficient to occupy their minds. They were fond of discussing public questions, questions of social science, and sanitary questions. Then there were many excellent men who saw and knew that there were a great many things bearing most unjustly upon the members of their profession, and who felt that the profession did not hold that social position which it ought to hold, and that some of its members got a very inadequate remuneration for their services; men of that class seize every opportunity to assert the rights of their profession. If the proposition were adopted a body of such men would be introduced into their Council, and possess the confidence of many in the profession, as they would represent its interest. But these gentlemen would not assist the Council in dealing with higher questions, and therefore he was opposed to adding to the number of members as proposed by the motion; and if the Council were not increased, some members must retire to give place to the new representation, and he did not know who could be asked to retire. If the Council was to hold control over the various interests and licensing bodies they must not be deprived of their representatives. On the other hand, no one could think of asking the Crown nominees to retire. If such men were taken from the Council, its weight and influence with all classes would be seriously diminished. He could not, therefore, meet the wishes of the memorialists by reducing the number of members. He thought the Council should do its duty as it had hitherto done, and as he believed they all desired to do, and however they might differ in their modes, the action should be carried out, and he agreed with Dr. Acland that this important matter should have been brought forward so inopportunely, when the Council had so much on its hands He must, therefore, vote against the motion.

Dr. **Andrew Wood**, having briefly replied,

Professor **Syme**'s amendment was put to the vote, and carried by 16 to 4. Upon being put as a substantive motion, the numbers were 18 to 4.

THE PHARMACY BILL.

The following motion by Dr. **Rumsey**, seconded by Dr. **Paget**—

"That a committee be appointed to consider and report on the bill for the regulation of pharmacy now before Parliament, in order that if it should appear desirable the opinion of the General Medical Council may be represented by petition to Parliament, or by memorial to Her Majesty's Ministers, before the said bill shall become law."

was ushered in by an elaborate speech, of which we give an abstract. Dr. Rumsey stated that the present bill ignored almost every recommendation of the committee of the Medical Council in 1865. In the first place, its provisions were not extended to Ireland. Moreover, there was no requirement that chemists and druggists should dispense prescriptions according to the Pharmacopœia. And further, the bill contained no prohibition against the practice of medicine or surgery by chemists and druggists. The committee of this Council recommended that pharmaceutical chemists should be subjected to some controlling body, but the bill contained no such security, and the public therefore were in danger of having a number of unqualified men let loose upon them, the consequences of which might be most dangerous to the public health and safety. Then opium, which was now so largely consumed in various ways was omitted altogether from the list of poisons in schedule A. He was in favour of extending the same legislative restrictions to the sale of this and other fatal poisons, as is done in the case of arsenic, for the purpose of identifying the purchaser. More satisfactory evidence of qualification should be required. What could be more monstrous than the present bill, which afforded protection to the lowest class of chemists and druggists, who might be mere grocers or common drapers, by permitting them to register as qualified chemists; and not only so, but extending their privileges to assistants also, even to those boys who had served two years' apprenticeship. A number of persons would thus be [illegible] should they live to become octogenarians, to poison the [illegible] under the protection of this bill, for fifty or sixty [illegible]. He, therefore, earnestly trusted the Council would not [illegible] to adopt the motion proposed by him, for, in considering the interests of the profession, they would also be defending the welfare of the public, whom they were bound in honour to protect.

Dr. **Leet**, as the representative of pharmacy in Ireland, entirely objected to the extension of the bill to that country in its present form, and to show how unwise it would be to do away with the wholesome regulation now in force, which forbade, under heavy penalties, anyone compounding or dispensing medicines without first having undergone the examination at, and received the certificate of the Apothecaries' Hall of Ireland, he would read a short extract from the report of the Queen's University, dated June 20th, 1855:—"The Senate has to observe that the practice of pharmacy is already provided for in Ireland by the Apothecaries' Act of 1791. This Act has worked well, and carried out its objects, especially in providing well educated Apothecaries for the public service; it therefore does not appear necessary to legislate for this department, neither does it seem important or desirable to alter the present state of the law." The Council would see by this why he opposed its extension to Ireland. The present regulations answered admirably, and for that reason, he hoped they would not be disturbed.

Dr. **Alexander Wood** considered that the Council and the profession at large, were deeply indebted to Dr. Rumsey for the care and labour he had bestowed upon the subject of State medicine, and for the elaborate and satisfactory arguments adduced by him on the important subject of pharmacy. He remembered some years ago there was an agitation on the pharmacy question, and a select committee was appointed for the same purposes, proposed in the present bill. Whilst admitting that much had been done since then by the Pharmaceutical Society towards the elevation of pharmacy, and it had therefore claims upon the Council that certain privileges should be extended, he was, nevertheless, opposed to the admission by law of this body to the status of the profession. They were essentially traders, and as a trading body were entitled to respect, but to incorporate them with the profession would have the effect of ruining the majority of the general practitioners in the empire. As the representatives of the whole profession therefore, he considered they should let their voices be heard before this bill—which, in some of its bearings, was very obnoxious—became law, and for this purpose he would support the proposition of Dr. Rumsey for the appointment of a committee.

Mr. **Cooper** expressed similar opinions.

Dr. **Aquilla Smith** objected to the quotation by Dr. Leet, relative to the pharmacy question in 1855. Since that time pharmacy had greatly degenerated in Ireland since the passing of the Medical Act in 1858, which was attributable to the monopoly held by the Apothecaries' Hall of Ireland, in fact, so low had it become, that a physician would have great difficulty to get a prescription made up by an apothecary in Ireland. He maintained, with Dr. Wood, that it was but a trading body, and he did not therefore see why the Society of Apothecaries in Ireland should demand an examination of the subjects which pertained to the study of medicine, which were not at all necessary for a chemist to know—on the pain of a refusal of a license to compound and dispense medicines. No chemist, however eminent—he might mention that were Mr. Squire, than whom few had done so much to elevate the science of pharmacy—would be allowed to open a shop for compounding prescriptions, under the penalty of a fine of £20. He desired to see a spirit of reciprocity between each division of the kingdom, considering it unjust that a monopoly should exist in Ireland, which gave the Apothecaries' Hall power to prohibit any person coming from England or any other part of the country, from following his business as a chemist, unless he first obtained the certificate from that body, whilst any one crossing the channel from Ireland, would be entitled to establish himself as where he chose without such a restriction.

Sir **Dominic Corrigan** stated that the extract quoted by Dr. Leet, from a report of the Senate of the Queen's University, of which he (Sir Dominic) had the honour to be a member, was given in 1855, and was, therefore, prior to the passing of the Medical Act, 1858. Circumstances and opinions had undergone a great change since then. He had recently received letters from two members of the House of Lords—asking his opinion to the working of the Medical Act in Ireland, and the Council would see what his opinions were if he read to them the clause he proposed to be introduced in the "Pharmacy Act, 1868," now passing the Houses of Parliament:—

"That from and after the passing of this act, every person duly qualified and registered under this act, and thereby entitled to open shop as 'compounding chemist' in Great Britain, shall in like be entitled to open shop as 'compounding chemist' in Ireland, without being subject to any prosecution or penalty, notwithstanding any enactment to the contrary in the Apothecaries' Act of Ireland, 1791."

He was not surprised that Dr. Leet should oppose the motion of Dr. Rumsey, because if it passed, it would virtually put an end to the extraordinary powers now possessed by the Society he represented, namely the double power of licensing in pharmacy and registering as medical practitioners, besides which a source of its income would be thereby stopped. As had been before stated, no man was allowed to compound medicines in Ireland, without having first obtained the licence of the Apothecaries' Hall. And what are the subjects enforced by this Society; they are: that a man should be examined in the principles and practice of medicine, diseases of women and children, midwifery, &c., &c. Why, should this be demanded of a compounding chemist, would the Council imagine for one moment that to be able to compound he must understand midwifery or be a good surgeon? It was simply ridiculous, and the effect it had in Ireland was this: that no man would settle down in Ireland as a compounding chemist, because if he had the money, and was compelled to pass such an examination, he preferred becoming a member of the profession of medicine or surgery on the completion of his education. He was therefore decidedly of opinion, that some of the provisions of the Pharmaceutical Society of Great Britain should be extended to Ireland, that the monopoly now possessed by the Apothecaries' Hall should henceforth cease, and that any man who could produce satisfactory evidence of his knowledge of pharmacy, with the certificates of the Pharmaceutical Society as a voucher, or from the Apothecaries' Hall of Ireland, that he should be allowed to compound medicine in any part of the United Kingdom he chose, without being subjected to the penalties now existing in Ireland.

Dr. **Acland** was of opinion that after the very lucid remarks of Sir Dominic Corrigan on the subject of pharmacy, little remained to be said. It was quite clear that a man should be either a chemist or a surgeon, and it was equally clear that no examination should be required as would fit him for both. As the powers now possessed by the Apothecaries' Hall of Ireland had not worked well, he hoped that the committee appointed by Dr. Rumsey would deal with it, and that the provisions should be the same in all parts of the United Kingdom.

The motion of Dr. Rumsey was then put to the vote and carried unanimously, the following gentlemen being appointed as the committee:—Dr. Rumsey, Dr. Acland, Mr. Cooper, Sir D. Corrigan, Dr. Alexander Wood, and Dr. Leet.

REPORT OF THE PHARMACOPŒIA COMMITTEE.

"The Pharmacopœia Committee appointed by the General Council for watching over the progress of pharmacy, and for making such additions and corrections as would facilitate hereafter the preparation of the next editions of the *British Pharmacopœia*, beg leave to report that, in accordance with the authority given them by the Council—(Minutes of June 3, 1867, vol. v., p. 136) to obtain such assistance as they might think necessary for carrying out the foregoing object, they engaged the services of Dr. Redwood, whose services had been so valuable in the preparation of the last edition of the work.

"In accordance with the request conveyed to him, Dr. Redwood has prepared and placed in the hands of the committee a report, which is well calculated to be useful in all further proceedings connected with the work. A portion of this report refers to some typographical and minor errors, which, though of no great importance, require correction in the *Pharmacopœia* of 1867. The committee recommend that this portion of the report should be published, so that those who possess the *Pharmacopœia* may themselves be enabled to make the necessary corrections; and the committee also recommend that these corrections be printed as a slip, in the copies hereafter sold.

"The committee beg leave to report that they have expended £25 of the sum of £50 placed at their disposal at the last session of the Council, and they recommend that a like sum of £50 be placed at their disposal for the next year.

"W. **Sharpey**, Ch[illegible]

"June 29, 1868."

Dr. **Quain** moved:—

"That the [illegible] authorized to pay [illegible] £50, voted by the [illegible] Committee of 1867, to be paid to Dr. Redwood for his special and extra services in the preparation of the work, but omitted in the amount submitted for payment to the Council at its last session."

Dr. **Apjohn** stated that the resolution proposed by Dr. Quain could not, in his opinion, be entertained, because it contained a statement which, in point of fact, was not correct. Dr. Apjohn went on to say that there was most certainly some misapprehension. The report of the Pharmacopœia Committee was made June 3, 1867. He had read it through more than once, and he was in a predicament to state positively that there did not exist in it any such recommendation as is assumed in the resolution of Dr. Quain. He was not, indeed, surprised to find Dr. Quain expressing himself in terms so irregular. During the existence of the committee to which the preparation of the Pharmacopœia of 1867 had been entrusted, he had found it very difficult to act in co-operation with Dr. Quain. A meeting was convened for the purpose of organizing machinery for continuing the operation of the Pharmacopœia Committee, and, in particular, for indicating a plan for watching over the progress of pharmacy, and for making such additions and corrections as would facilitate hereafter the preparation of the next edition of the Pharmacopœia. The meeting of the committee he (Dr. Apjohn) of course attended, but when the members were, as he conceived, about to consider the important subject for which they were called together, Dr. Quain announced to them that he had already a plan proposed, and that it was quite unnecessary for the time of the council to be taken up with the consideration of a matter for which he had already provided. Dr. Apjohn, therefore, thought it necessary to state that he would no longer act on the committee. After this explanatory statement, into which he said that he had entered in his own justification, Dr. Apjohn moved the following amendment on Dr. Quain's motion:—

"That there has been no recommendation from the Pharmacopœia Committee to pay to Dr. Redwood £50 for what are called special and extra services in the preparation of the Pharmacopœia, and that, under such circumstances, it is not in the power of the General Medical Council to allocate any sum, however small, to the purpose specified by Dr. Quain."

After further discussion the Council adjourned.

Thursday, July 3.

Dr. **Aquilla Smith** took exception to the manner in which Dr. Redmond's report had been brought before the Pharmacopœia committee, which met on Monday, 29th June. The report had not been seen by Dr. Christison, or by Dr. Smith, and no opportunity had been given to the members of the committee not residing in London, of making any suggestions respecting the matters mentioned in the report. Dr. Smith expressed his approbation of the tenour and matter of Dr. Redmond's report, and, at the same time, that he regretted not having had an opportunity of suggesting many particulars similar to that portion of the report which the committee recommended in their report to be printed. Dr. Smith submitted his resolution, and explained that his object was to place before the profession the suggestion for the improvement of the Pharmacopœia, in order that they might be considered.

Dr. **Sharpey** expressed it as his opinion that the objection raised by Dr. Apjohn could be satisfied by substituting the term "voted" for that of "recommended" in the motion of Dr. Quain.

This suggestion was accepted by Dr. **Apjohn**, who then withdrew his amendment.

Dr. **Quain** regretted that Dr. Aquilla Smith had not been a member of the committee *ab initio*, or he would not have complained of the mode of proceeding. Dr. Aquilla Smith's suggestions would have been most acceptable. It was his own fault, if that of any one, that they were not offered. The report could not have been submitted to the committee until the committee met, in fact, the report was in the hands of the committee within a few hours of its receipt. The report may or may not be published as the Council might think fit. It was proposed as a record for future use, and not for publication, but the committee had no objection to the publication, though they thought it neither necessary or desirable.

Dr. **Andrew Wood** was of opinion that no committee should be appointed for the ensuing year, as he saw no good from the last, thereupon

Dr. **Quain** withdrew his motion, and, at the same time, expressed a desire, owing to the great labour it entailed upon him, and the few thanks he obtained for his work, to withdraw from all connection with the committee.

The subject then dropped.

The Council then adopted a report from the committee on lunacy certificates, recommending that a letter be addressed to the Home Secretary on the subject, as follows:—

REPORT OF THE COMMITTEE ON LUNACY CERTIFICATES.

Abstract of Letter to the Home Secretary as to Medical Certificates in Lunacy.

SIR,—I am directed by the General Medical Council to a difficulty which has arisen on the construction of the Lunacy Acts for England, Ireland, and Scotland, with reference to the medical certificates which are necessary to authorise the detention of a lunatic in an asylum.

By the English Act 8 and 9 Vict., cap. 100, sec. 45, such certificates are to be signed by "two physicians, surgeons, or apothecaries," who shall not be in partnership, and a false certificate is punishable as a misdemeanour.

By the Scotch Act 20th and 21st Vict., cap. 71, sec. 34, such certificates are to be signed by "two medical persons, one of whom may be the medical superintendent or consulting physician of a public or district asylum." And the giving a false certificate is made an offence punishable by a penalty not exceeding £300, or imprisonment not exceeding twelve months.

By the Irish Act 5 and 6 Vict., cap. 123 (continued by subsequent acts), secs. 14 and 15, such certificates (sec. 14) are to be signed by two physicians, surgeons, or apothecaries, and (sec. 15) by two medical practitioners not being in partnership, and each of them being a physician, surgeon, or apothecary.

By the Medical Act (1858), 21 and 22 Vict., cap. 90, sec. 31, every person registered under that act is entitled to practise in any part of her Majesty's dominions; and by sec. 37, no certificate required by any act then in force, or that might thereafter be passed from any physician, surgeon, licentiate in medicine and surgery, or other medical practitioner, shall be valid, unless the person signing the same be registered under that act.

The question which has arisen is, whether the certificate of a practitioner resident in England is sufficient to authorise the detention of a lunatic in Scotland or Ireland, and *vice versa.*

This question in 1867 was submitted to you by the General Board of Commissioners in Lunacy for Scotland. You took the opinion of the law officers of the Crown, and the following communication was made by your direction to the Board of Commissioners:—

"I am directed by Mr. Secretary Hardy to inform you that he has laid a case before the law officers of the Crown, and that they are of opinion that upon the true construction of the statutes certificates signed by medical men in Scotland do not constitute a valid authority for the detention of lunatic patients in England and Wales, and *vice versa.* The same rule plainly applies to such certificates granted by medical men in Ireland."

It will be observed that the language of the several lunacy acts is quite general on the subject, and the grounds on which the opinion of the law officers was formed is not stated. Probably, however, the opinion was founded upon some such considerations as are stated in the 20th report of the Commissioners in Lunacy in England, page 48, as follows:—

"Connected with this subject it also became necessary that we should point out, in the course of the present year, that certificates signed by medical men in Scotland, in Ireland, or in any place out of England and Wales, do not constitute a valid authority for the detention of lunatic patients under an extract which is expressly restricted to England and Wales. It had been the practice to receive within the time specified in the statute, the certificate of registered or or other practitioners possessing the proper qualifications set forth in it, even though they might have signed in a place not situate in England or Wales; but upon the commissioners having had their attention called to a case in which the question was specially raised, it seemed to them to be among the strict requirements of the Lunacy Acts that all persons signing a certificate should not merely be duly qualified under them, but should also, by residence within the jurisdiction, be responsible for the penalties expressed in them for irregularities contravening their provisions; and that a person against whom such penalties could not be recovered in the event of illegality or irregularity being found in the certificate signed by him, is not a person whose certificate is contemplated by the act, or receivable under it. The commissioners regret to have arrived at a decision which has been complained of as closing the door of English asylums to the patients of medical men practising in Scotland and Ireland, but the law leaves no alternative; and as this rule will in future be strictly enforced, it is necessary that all alleged lunatic persons whom it may be desired to place in hospitals or licensed houses within the jurisdiction of the commissioners, should first be brought to some place within that jurisdiction, with a view to the necessary personal examination, before certificates can be signed."

Considering the importance which these certificates have as affecting the liberty of her Majesty's subjects, it must be admitted that the objections stated by the Commissioners in Lunacy are entitled to great weight, but at the same time the adoption of the rule infringes the privileges conferred on the medical profession by the Medical Act, and leads to considerable inconvenience when it is desired to place a lunatic in an asylum which is not in that part of the United Kingdom where the lunatic resides. The object can only be effected by bringing two medical gentlemen from England, Scotland, or Ireland, as the case may be, to the place of the lunatic's abode, or by taking the lunatic, without any legal authority, from his abode to that part of the United Kingdom where the asylum in which it is desired to place him may be.

I am instructed to suggest to you that an act should be passed, applicable to the United Kingdom, which, while it will give to the medical profession the full privileges contemplated by the Medical Act, will at the same time ensure that no person giving a false certificate shall escape the punishment justly due to his offence.—I have the honour to be, sir, your most obedient humble servant, &c.

The Right Hon. Gathorne Hardy,
Home Secretary, Whitehall.

The following report of the Committee on Vaccination was next received, and a proposal was made by Mr. Cæsar Hawkins for the issuing of recommendations to the licensing bodies that they should require from every candidate for their degrees or diplomas a certificate that he had studied vaccination under a competent and recognised teacher at some school or hospital providing ample means of study. This was opposed by Sir D. Corrigan, who said he considered the proposed certificates worthless, and moved an amendment recommending direct examinations in vaccination by the licensing bodies. After a full discussion the amendment was put and lost, and the motion of Mr. C. Hawkins was adopted, as was also a letter proposed by the committee to be addressed to the Medical Department of the Privy Council embodying the recommendations of the Medical Council.

Although the legal power of the Privy Council in enforcing vaccination relates only to England, yet, considering the great importance of the subject, and the general objects of the Medical Act, the committee consider that it is the duty of the Council to endeavour to further the views of the Privy Council towards improving the knowledge of this subject in all parts of the United Kingdom.

It is the object of the Privy Council "that the fact of a person's admission to the Medical Register, or at least his admission under some particular title or titles therein, would virtually guarantee his being thoroughly skilled in vaccination," and thus do away with the necessity for the special certificate which the Privy Council have hitherto required from every contractor for vaccination in England, whatever may have been the source of his medical qualification.

The Branch Council for Scotland report (vol. v. p. 305) that all registered practitioners are allowed to certify as to vaccination, that the existing Vaccination Act has been very successful, and that as far as Scotland is concerned there is no necessity for further change. The Branch Council are, however, of opinion that "it might be well that all examining boards should require every candidate for their licenses to produce a certificate from a dispensary or other public institution where vaccination is practised attesting that he has been practically instructed in the operation, and is acquainted with the appearances which follow its performance."

Responding to this expression of opinion (see minutes of Branch Council, February 21, 1868), the Universities of Edinburgh, Aberdeen, and Glasgow, the Royal College of

Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, all agree to require a certificate from public bodies only. The Royal College of Physicians of Edinburgh think certificates from special vaccinators unnecessary, but recommend their examiners to examine every candidate as to his knowledge of the practice of vaccination and of the progress of the vaccine vesicle.

The Irish Branch Council (see minutes, vol. v., p. 347) approved the objects of the Privy Council, and requested the opinion of the qualifying bodies.

The University of Dublin recommend their students henceforward to obtain instruction in vaccination at the Cow-Pock Hospital.

The Queen's University in Ireland, and the King and Queen's College of Physicians in Ireland, place no dependence on certificates, but will draw the special attention of their examiners to the subject, with the object of their testing the knowledge of candidates in this branch of medicine. Both bodies say that they are not aware of any complaints in Ireland on the subject. The College of Surgeons in Ireland is of opinion that every effort is made by their examiners to secure proficiency in the performance of all surgical operations, vaccination included. The Apothecaries' Society in Ireland already require certificates from a public vaccine institution, or from an authorised vaccinator, and will in future require candidates to pass an examination in all that relates to the due performance of vaccination.

The English Branch Council expressed an opinion that the subject of vaccination required the early and serious attention of the General Council, and requested the president to draw the attention of the English licensing bodies to it.

The committee regret that no communication has been received from the University of Oxford or the Society of Apothecaries.

The Medical Board of the University of Cambridge think it advisable that arrangements should be made at all medical schools for efficient instruction in vaccination, and that all candidates for medical or surgical practice should produce a certificate of having seen the process of vaccination in a certain number of cases.

The University of Durham will hereafter require examination as to vaccination of all candidates for a licence in medicine or surgery.

The University of London will hereafter require a certificate from one of the authorised vaccinators appointed by the Privy Council, and that every candidate shall be practically examined in vaccination.

The Royal College of Physicians of London will hereafter require a certificate from vaccinators appointed by the Privy Council, or from recognised teachers of vaccination in medical schools, that the students themselves have performed the operation, and are thoroughly skilled in vaccination; and the college called the attention of the examiners to the importance of ascertaining the competency of all candidates in the theory and practice of vaccination.

The Royal College of Surgeons of England state that they believe that the steps taken by them in 1859-60 are such as to secure proper instruction and proficiency in vaccination; that the certificate required from all candidates was especially framed with that object; which certificate may be given by any fellow or member of the college, when ascertained by a duly authenticated certificate that he possessed the necessary opportunities for the proper instruction of the pupil in this operation in surgery.

The college observes in addition, that as these certificates have only been enforced since Oct. 1st., 1860, sufficient time has not elapsed to enable the Lords of the Privy Council to judge fully of the effects of that requirement as affecting the efficiency in that branch of surgery of fellows or members admitted subsequently to that date.

This observation appears to the committee to possess considerable weight in reference to the proportion of new vaccinators contracted with annually to the whole number of medical practitioners employed under the Poor-law Board in England.

From consideration of these documents, and the knowledge thus acquired of the sentiments of almost all the licensing bodies, and from such further information as they have been able to obtain, the committee are led to believe that imperfectly performed vaccination is only one of several causes of the prevalence of small-pox; but still, in order to obviate this deficiency as far as possible, they venture to propose that the Council should sanction, and issue to each licensing body in England, Scotland and Ireland, for their adoption, the following recommendations:—

1st. That a certificate should be required by each licensing body from every candidate for its degree, diploma, or licence to practice medicine or surgery, that he has studied vaccination under a competent and recognised teacher; that he has himself performed the operation successfully under the teacher's inspection; that he is familiar with the different stages of the vaccine vesicle, and with the methods of preserving lymph, and is thoroughly informed in every necessary part of the subject.

2nd. That such a certificate should only be received by any licensing body from recognised vaccine stations, or from recognised vaccine departments in medical schools, or hospitals, or other public institutions, where the appointed teacher of vaccination is not liable to frequent change, and where ample means for study are provided by not less than such a number of cases (perhaps 8 or 10 on an average weekly) as may be found, after due inquiry in the first instance, confirmed by authentic returns, or inspections from time to time, to be sufficient for this purpose at each place.

It is obvious that for the two-fold object of the proper study of vaccination and the preservation of a due supply of lymph for national purposes, only a small number of stations or schools for vaccination can be provided in each division of the United Kingdom, with a sufficient and continuous number of cases.

The committee are informed with regard to Ireland, that although certificates in vaccination are in practice chiefly given from the Cow-Pock Hospital in Dublin, yet they might possibly be received from any one of many hundred public dispensaries, whose opportunities for instruction will therefore require investigation in every instance before certificates from them can be considered trustworthy.

Again, with regard to England, although the very small number of vaccine-teaching stations nominated by the Privy Council, in London, and a few provincial towns may, perhaps, after the inquiry suggested by the committee, be somewhat enlarged with increased convenience to medical students, and without interfering with the views of the Privy Council for the national welfare, yet, on the other hand, the wide latitude granted at present by the Royal College of Surgeons of England to its fellows and members will henceforward cease under the limitations recommended by the committee.

In conclusion, the committee submit a draft letter to the medical department of the Privy Council Office for the consideration of the Council.

Cæsar H. Hawkins, Chairman.

The Medical Council trust that considerable improvement has taken place since that time, as to the knowledge of vaccination, by the action of some of the licensing bodies, who have required proof of competence from a large number of persons admitted in the last few years to the *Medical Register* which would every year have been more sensibly felt as the proportion of persons thus taught became larger relatively to the whole of the medical profession.

The Medical Council beg to assure the Lords of the Privy Council that they have found the greatest desire on the part of the universities and medical corporations generally to forward their lordships' views regarding vaccination, and entertain no doubt of their concurrence in such measures as may be considered necessary still further to secure this object.

The Medical Council, on mature consideration of the question in relation to the whole empire, have agreed to issue to all the licensing bodies placed by the Medical Acts under their control, recommendations to the following effect:—

1. The Medical Council entertain a confident expectation that by the general adoption of these recommendations great improvement will be produced in the method and extent of the teaching of vaccination, and that a complete and practical knowledge of the whole subject will be enforced upon every person who seeks admission to the *Medical Register*, so as to secure the proper performance of the operation, and subsequent observation of its effects.

2. The Medical Council believe that, when the proposed system is fully in operation, the Lords of the Privy Council may be led to feel that confidence in the skilfulness in vaccination of all persons hereafter admitted to the *Medical Register* which would enable their lordships, as they desire,

to dispense with the special certificate now required from contractors for vaccination in England.—I have the honour to be, sir, your obedient servant,

Francis Hawkins, Registrar.

Dr. Acland then rose to move the following motion, the discussion on which was adjourned to the following day, and the meeting separated:—

"That the treasurer be authorised to pay £100 to Dr. Richardson, F.R.S., to aid him in his researches into the class of agents which can with safety be used as Anæsthetics; that one-half be forthwith paid, and one-half on presentation of a report, which shall have special regard to the several properties of the said agents, and their fitness to be introduced into the British Pharmacopœia."

Friday, July 4.

The Council met in private conference from one till two o'clock, in order to elect a president vice Dr. Burrows, whose tenure of office would expire before the meeting of the next Council.

At two o'clock the proceedings commenced as usual, by the reading of the minutes of the preceding day, and these being confirmed, it was announced that the differences existing on the previous day, relative to the appointment of the Pharmacopœia Committee for the ensuing year, and the additional grant to Dr. Redwood, had been arranged to the satisfaction of Dr. Quain, and the appointment of the same gentlemen who acted upon it during the past year was agreed to, Dr. Aquilla Smith's name being included on the list.

The adjourned debate on the motion moved by Dr. Acland at the close of yesterday's proceedings was resumed.

After a discussion, occupying nearly two hours, on the propriety and legality of the proposed grant, it was ultimately agreed to—"That the motion be not put to a division," by permission of the Council. It was then withdrawn.

Dr. Andrew Wood, on behalf of Mr Syme, who was unavoidably absent, reported that the committee on the subjects of medical education, after taking into consideration the points referred to them, have put in train a series of arrangements by which they hope to be able to obtain valuable evidence from the principal teachers and examiners in the kingdom which may aid the committee in drawing up a complete report for the next meeting of the Council.

The report of the Finance Committee was next submitted to the Council.

Moved by Dr. Storrar, and seconded by Sir Dominic Corrigan:—

"That the report of the Finance Committee be adopted."

Amendment, moved by Mr. Hargrave, and seconded by Dr. Rumsey:—

"That instead of £35, recommended by the Finance Committee to be given to Mr. Bell and Mr. Roope, an addition of £50 be made to the salary both of Mr. Bell and Mr. Roope."

The amendment was carried.

Moved by Dr. Parkes, seconded by Dr. Apjohn, and agreed to:—

"That the best thanks of the Council be given to the Director-General of the Army Medical Department; to the Director-General of the Navy Medical Department; and to the Right Honourable the Secretary of State for India, for their kindness in furnishing to the Council the returns of the examination of candidates for the respective medical services of the army, navy, and India."

The application from Dr. Frederick Milford to be registered as M.D. (by examination) Heidelberg, 27th June, 1856, was unanimously acceded to; and the letter from Dr. James Mason, relative to the Medical Acts Amendment Bill, was ordered to be received and entered on the minutes.

A communication from the Branch Council for Ireland, relative to two applications for registration in the "Student's Register," was acknowledged, and the course taken approved.

Upon the letter from Dr. Edwards Crisp, relative to the adjudication of the Carmichael Prize, being brought before the Council,

Mr. Hargrave rose to move that it was not within the province of the Council to give its opinion thereon. The Council of the College of Surgeons of Ireland had always acted wisely, legally, and with the utmost impartiality; he therefore contended that it was not a matter in which they could or should feel desirous to interfere.

With Mr. Hargrave's remarks the Council were agreed, and the matter then dropped, Dr. Alexander Wood naively suggesting, amidst considerable merriment, that the subject be referred to the Committee on Lunacy.

The second letter from Dr. Edwards Crisp, on the increase of half-qualified practitioners, since the passing of the Medical Act (1858), &c., was ordered to be entered on the minutes, and referred to the Committee on "The Licensing Bodies and Registration of Students."

A memorial from the North of Scotland Medical Association relative to the position of parochial medical officers, was acknowledged, intimation being given that it was not within the province of the Council.

A letter from Dr. R. Barnes, relative to the use of his surname by a non-registered person, in offensive advertisements, was read by Dr. Bennett, its justice acknowledged, and the general purport ordered to be entered on the minutes.

The report of the Committee on Preliminary Education, was then gone into, and occupied the attention of the Council until six o'clock, at which hour the debate was adjourned.

Saturday, July 4.

The Council were engaged nearly the whole afternoon in a discussion on the series of proposals of Dr. Alexander Wood, the chairman of the Committee on Preliminary Education, which, owing to the extreme length of the debate on the reform of the Medical Council, we are compelled to omit this week, as also the report and the debate on the "Report of the Pharmacy Committee," including the regulations on the scale of poisons, which was proposed by Dr. Rumsey, who has bestowed much labour to bring this important matter before the Council, with a view to the presentation of a petition to Parliament before the Bill "The Pharmacy Act, 1868" becomes law, and seconded by Mr Hargrave.

Some of the suggestions contained in both reports are exceedingly valuable, and we therefore purpose giving them *in extenso* in our next number.

Monday, July 6.

The Council met to-day two hours earlier than usual, in order that the business of the session might be concluded before rising. The various questions before them were accordingly disposed of, and the session, which has lasted longer than usual, was concluded with the customary votes of thanks to the President, the Council of the College of Physicians for the use of the rooms, to the officials, &c.

The debates of Friday, Saturday and Monday will be given in our next.

◆

DR. CHARLES DRYSDALE ON PROSTITUTION.

At two full meetings of the Dialectical Society on the evenings of May 18 and 25, at which were present, among others, Lord Amberley, vice-president of the society, Mr. M. Conway, Mr. Acton, Dr. Prosser James, Dr. Oppert, Mr. Nasmyth, Dr. Edmunds, Dr. Chapman, Mr. Dyte, &c., a paper was read on the causes and consequences of prostitution by Dr. C. R. Drysdale, Physician to the North London Hospital for Consumption. The author observed that there might be said to be about 10,000 prostitutes in London and 5000 in Paris; but the importance of this class of unfortunate women, and the part they played in spreading contagious diseases of a most dangerous kind, made the class one of the most interesting to the philanthropist and to the medical man. The chief causes of prostitution were the sex appetite, a constant force like gravitation always impelling the sexes towards each other. Then came, as subsidiary causes of prostitution, the love of dress, idleness, want of education, the decrease of marriages in Europe, drunkenness, and, above all, the low wages of the female sex. The sex appetite, being dependent on organism, could not, and ought not, he thought, to be *lessened*, but only to be *regulated*. The love of dress was a cause of prostitution in many instances, and also the desire to get money without toil, which was, indeed, the cause of many of the vices of both sexes. *Want of education*: In Bordeaux, of 105 prostitutes, only 9 could sign their names. *Idleness* was often caused by the low remuneration of female labour. *Poverty* was the most fruitful cause of the venality of women. The wages of some workwomen was deplorably low. Thus, Dr. Edward Smith had given, in the sixth report of the Privy Council, a statement, that many needlewomen only earned 3s. 11½d. a week on an average. *Decrease of marriages* was observed in all European States, owing partly to the irrevocability of the contract, and to the difficulty of rearing offspring in the already crowded state of society of old countries. In Paris one-third of the births were illegitimate. In Munich more than half. Dr. Drysdale showed the extreme frequency of venereal diseases in London and elsewhere, by mentioning that 43 per cent of the out-patients of Guy's Hospital were said to suffer from the diseases which were kept up by prostitution. He spoke of the sterility of prostitutes, as accounting for the existence of the class: in Paris 1000 of these women do not produce one child a year among them; were it otherwise, infanticide would be far more prevalent than even at present. Prostitutes were rather healthier than the average of the female sex, with the exception of suffering from venereal diseases. Hysteria, especially, was rare among them, probably owing to the latter disease being more common among women who lived a life of celibacy. Dr. Drysdale hoped that before long society should have been sufficiently enlightened to desire to stamp out such foes to life as the venereal diseases, by admitting prostitutes, when diseased. immediately into hospitals, and also by encouraging them to attend to cleanliness and to their own health, by scrupulously avoiding contagion from their visitors. But the chief means of *preventing* prostitution was to raise the wages of women, by enlarging their industrial employments, and educating them in science and industry. As long as families were so large in overcrowded countries, so long would poverty and its attendants—degradation, filth, and vice—abound. Should mankind, however, ere long, become tired of the prevalent theological dogmas about the necessary degradation of human life, and take their own destinies in their own care, and have only that number of children which was compatible with good wages and the full employment of all, prostitution would disappear; and he, Dr. Drysdale, fully believed that, eventually, this would take place. He approved of great facility of divorce, as in Indiana, U.S., as a remedy against prostitution. In Indiana, six months and the will of either party suffices.

Mr. Conway (of Virginia) said, that in no part of the world had he seen so much domestic happiness and fidelity, as in Indiana, U.S. The reason of this was, that divorce was at the will of either party; and thus marriage became a real joining of congenial natures. Poverty was the great cause of prostitution. Wherever women had low wages there was prostitution, as in New York and London; in Indiana, &c., there was none of it.

Mr. Levy. although agreeing with the two former speakers, that a facility of divorce was desirable when women were able to gain good wages, thought that in overcrowded countries like this it would be injurious to the interests of women. Women's employments should be extended first.

Dr. Chapman thought that it was as well to do half a good if we could not do *all* that was needed. It was cruel to keep together persons not *truly* married, as this law favoured infidelity and prostitution. Prostitutes should be admitted into hospitals when diseased, which hitherto religious bigotry had opposed. Registration of prostitution and police supervision was much opposed to justice, and the matter should be openly and freely discussed, since the problem was one of the most important of all those of social science. Sexual appetites were too strong and ungovernable, in proportion to the other appetites, at the present time.

Mr. Smith also believed that the appetite of sex was capable of being much lessened as civilization advanced, and culture extended.

Mr. Fox Bourne contended that those women were not to blame, who when very ill-fed and starving, took to prostitution. On the principle of the "greatest happiness" they certainly gained more than they lost by so doing. And, as they were reported to be barren, prostitutes often were much less injurious to the working classes or receivers of wages, than those wives who were mothers of large families, and who brought low wages and starvation upon their unhappy offspring. He thought the police examination of prostitutes no more an infringement on liberty than other hygienic regulations, such as emptying dust bins, &c. Women should be more employed in industry.

Mrs. Frith (formerly matron of the British Lying-in Hospital), did not agree in the views stated as to the facility of divorce. She would have divorce more difficult, in order to protect women more. Women ought to be educated well and enabled to get their own living. Novel reading was dangerous to female virtue, and alcoholic drinks given to children tended in this direction. The overcrowding in towns was injurious. Many poor girls would gladly return to industry, could they see their way to do so, and many of them had shown charity and great kindness to their poor relations. Emigration [illegible] women should be much encouraged to countries where they were less crowded than here.

Dr. Edmunds dilated on the importance of providing occupation for women. The emigration of men had left such a disproportion between the sexes in this country that, when a paltry situation, such as that of governess, was vacant, a perfect host of applicants were always found ready to compete for it. Industrial employment for women was the grand remedy for prostitution. Women should be made to be independent.

Mr. M'Gregor Allen said that the present laws of legitimacy were a disgrace to civilization. A mother of an illegitimate child received only 2s 6d. a-week, and was thus forced into prostitution or infanticide. The grand cause of prostitution was poverty, and this, as was well-known, was due to the large families so common in this country and in many other over-peopled states. Chastity was *not* the greatest virtue in women.

Mr. Laurie said it was a farce to suppose that a poor girl, earning only 2s. 6d. a week could be expected to be chaste, when she would only starve as an alternative to becoming a prostitute.

Dr. Oppert said that England was now the great obstacle towards the stamping-out of venereal diseases.

Dr. Roberts, although opposed to large families, was also averse to industrial employment of women. It made them bad wives.

Mr. Gough thought that production would be increased if women were employed; and thus there would be more for society to consume.

Mr. Nasmyth spoke of education as the great want. The appetite of sex had hitherto been ignored as one of the imperative wants of human beings. It must not be ignored, but regulated, in future, and then prostitution might disappear.

Mr. Acton had been greatly pleased with the debate. Prostitution was an inevitable evil *at present*. How could its ill effects be palliated? Most prostitutes led this life for a year or two, and then got married. They did not die. but were usually very healthy, having good food and an easy life. Much might be done to render prostitution less dangerous to public health, and he had been deeply gratified with hearing a lady express her opinion. This led him to remark that if prostitutes could be advised to keep themselves more cleanly, and also to examine very carefully their customers, as they almost universally now did in Paris, they might themselves escape infection, and also assist in stamping out these serious contagions. How far it was advisable in this country to carry out the continental system of registration and police examination of prostitutes, he was not quite sure; but, at any rate, ample hospital accommodation for diseased women should be secured. At present it was scandalously inadequate. Persuasion and humanity would, he believed, effect as much as force in this matter.

Correspondence.

ON DINING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—One of the most important questions, in a sanitary point of view, for the medical profession to solve, as regards their patients and themselves, is *How and When to Dine?*

Many of our social habits require reforming, and they are only tolerated and kept up because no one is courageous enough to commence the necessary innovations. The prevailing manner of dining in fashionable society, for instance, is conducive neither to health nor comfort; faint grumblings find their way into the papers occasionally on the subject, but the complaints are only heard in a whisper, so they soon die away and are forgotten.

Now, when an evil of this kind is generally felt, but feebly suffered to go on, it is well for some one to come forward and attack it in an out-spoken way. I venture to undertake that duty, and I feel sure I shall have the support of your readers in bringing forward the present suggestions. There can be no question that heated rooms, bad ventilation, and late hours, render the present style of dinners a great infliction upon all persons who possess rational ideas on the subject.

There are people, of course, and, I suppose, always will be, who take a strange delight in sacrificing health to fashion, and are content to live a life of senseless excitement, if even they [illegible] the effort to carry on such an abnormal existence.

Above all things the dinners require to be under sanitary regulation; they should be very much simplified and curtailed. Somebody lately wrote to one of the morning papers to complain of the inconvenience of dining hurriedly in order to be in time for the opera. Imagine under what difficulties the digestive processes must be carried on in a heated atmosphere, immediately after partaking of a steaming and a hurried repast; it is not, moreover, the best preparation for an intellectual treat. I propose that a more simple meal should be introduced, at a much earlier or a later hour, than that which is now the rule: a kind of "meat tea" at five o'clock or at nine, would conduce much to health and economy, and we should thus get rid of the daily heat, worry, and other discomforts attending a two hours' sitting at a fashionable dinner.

The idea of a number of people being invited to meet together for the purpose of eating, is not a refined one; the chief object of an entertainment should be intellectual; refreshments more or less elaborate could be introduced incidentally.

We are not entitled to the distinction which we, English claim, of being the most civilized nation in the world, while we continue to make Dining the chief mode of entertaining our friends, and cherish a kind of faith in the idea, that to give "good dinners" is the only means of keeping up our position in society, and of conciliating that exacting, meddlesome, busybody, "Mrs. Grundy."—I am, Sir, yours obediently,

July, 1868. Sanitas.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

A meeting of the Central Committee of this Society was held in the Royal College of Surgeons on the 1st inst., Dr. Fitzpatrick in the chair.

Dr. Wharton announced that he was authorized to tender Dr. Duke's resignation of the office of Honorary Treasurer, in consequence of his continued ill-health.

Dr. Walsh then proposed, and Dr. Stewart seconded the following resolution, which was unanimously agreed to:—

"That Dr. Duke's resignation be accepted, and that the cordial thanks of this Committee be presented to Dr. Duke, for the efficient manner in which he discharged the duties of the Honorary Treasurer to the Royal Medical Benevolent Fund Society for the past six years, and that this Committee can not be satisfied with a mere formal acknowledgment of Dr. Duke's services, but beg leave to take advantage of this opportunity to express their deep regret at the cause which has led to his resignation, and to express an earnest hope that his retirement for a time from professional pursuits will have the effect of producing a restoration of his health.

Proposed by Dr. Quinan, seconded by Dr. Walsh, and resolved:—"That Dr. James Little be requested to accept the office of Honorary Treasurer of the Royal Medical Benevolent Fund Society of Ireland."

The following awards were made by the Central Committee during the past month—subsequently to the annual distribution:—

1. A widow, æt. 50. Husband dead some years. This was a case which has been annually relieved, but the application was received too late for the general distribution. Recommended by Sir Dominic Corrigan, Bart, and Dr. Benson. Granted £5.

2. Three female orphans; father dead three years. Application late for annual distribution. Recommended by Limerick Branch for a *final* grant of £15 to assist them to emigrate. Granted £15.

3. A spinster. For several years a recipient. Application late for annual distribution. Recommended by Limerick Branch. Granted £4.

4. A medical man, totally unable, from heart disease, to follow his profession; has six children, and no means of support. Recommended strongly by the Cork Branch. Awarded £15. This was an urgent case, and had come under the notice of the Cork Branch subsequently to the annual distribution.

5. A widow, æt. 70. Relieved last year. Friends supported her, but are now all dead. Recommended by Clare Branch. Awarded £5.

The Honorary Treasurer, Dr. Little, reported that from the unexpected calls upon the funds of the society (owing to the arrival of several applications after the annual awards had been made), there remained in bank to meet the awards to the last two cases not quite £5. It was, therefore, ordered that £4 be immediately sent to case 4, as most urgent, and that as funds were available the balance should be remitted; as also the amount of the award to case 5.

◆

Medical News.

The Public Health.—In the week that ended on Saturday, June 27, 4776 births and 2997 deaths were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 24 per 1000 persons living. The annual rate of mortality last week was 24 per 1000 in London, 24 in Edinburgh, and 18 in Dublin, 21 in Bristol, 18 in Birmingham, 27 in Liverpool, 27 in Manchester, 20 in Salford, 31 in Sheffield, 31 in Bradford, 20 in Leeds, 25 in Hull, 22 in Newcastle-upon-Tyne, and 29 in Glasgow. The rate in Vienna was 28 per 1000 during the week ending the 20th instant, when the mean temperature was 3·3 deg. Fahr. higher than in the same week in London, where the rate was 20. The deaths registered in London during the week were 1454. It was the twenty-sixth week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1304. The deaths in the present return exceed by 150 the estimated amount, and exceed by 226 the number recorded in the preceding week. The mortality from diarrhœa exhibits a considerable increase. In the week which ended the 6th of June, the deaths from diarrhœa were 27, in the two following weeks 31 and 66 persons died, and last week the deaths recorded were 171. It is essential at the present critical period of the year that the greatest care should be taken by the engineers and others, who have the control of the water supply of London, so as to prevent any contamination of the water. The ventilation of the sewers also demands attention. Professor Franklin says that "The long-continued drought has rendered the river waters supplied to London unusually pure. The previous sewage contamination of these waters is on the average much lower than has ever before been observed. The Southwark Company's water was again turbid from the presence of much suspended matter; besides giving the water a repulsive appearance, this suspended matter is nitrogenous, and therefore highly objectionable. With the exception of the East London Company's water, which contained, however, only traces of suspended matter, the rest of the samples were perfectly bright and transparent." At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·869 in. The highest day temperature was 88·0 deg. on Saturday, June 27. The lowest night temperature was 48·4 deg. on Tuesday, June 23. The highest reading of the thermometer in the sun was 157 deg. on Saturday, June 27. The mean degree of humidity of the air was 68, complete saturation being represented by 100. Rain fell to amount of 0·29 in. The general direction of the wind was S.W. Ozone was observed on six days during the week; the greatest amount was on Monday, June 22.

From the House of Commons on Friday last the following business is reported:—

Medico-Legal Inquiries.—Mr. Clive inquired whether the government had determined to appoint a Royal Commission to inquire into the present mode of conducting medico-legal inquiries, and as to the operation of the sanitary laws. Mr. G. Hardy said that the government had not lost sight of this subject, and they would see what was a proper inquiry to constitute in reference to it.

Austria and the Cattle Plague.—In reply to Mr. Moffatt, Lord Stanley said he was aware that the Lower House of the Reichsrath had passed a bill having for its object the prevention of the introduction of the cattle plague into Austria from Gallicia or Hungary, but not having yet received a copy of it he could not say what were the exact provisions of the measure. He had, however, written for a copy of the bill, and hoped to receive it shortly.

Poor-law and Medical Inspectors (Ireland) Bill.—This bill passed through committee.

Poor Relief (Salary of Auditors)—The report authorising the payment of these salaries was brought up and agreed to.

Burials (Ireland Bill).—This bill was read a third time and passed.

THE JOURNAL OF THE IRISH MEDICAL ASSOCIATION.

The unusual pressure on our columns from the reports of the General Medical Council, compels us, although we have increased the size of the Journal for their accommodation by one-third, to forego the publication of The Journal of the Irish Medical Association for one week. We have felt ourselves excused in doing so, because the important debates on the representation of the medical practitioner in the Medical Council embodied in the report are of such close and immediate interest to the Irish provincial practitioner that, under any circumstance, it would have been necessary to lay them before the readers of the Association Journal. We have in type an abstract of the Poor-law Commissioners' report just issued, which we hope to give in our next.

COPY OF "MEDICAL PRACTITIONERS' (COLONIES) BILL."

Whereas by the Thirty-first Section of "The Medical Act," passed in the Session holden in the Twenty-first and Twenty-second Years of Her Majesty, Chapter Ninety, it is enacted as follows:—"Every Person registered under this Act shall be entitled, according to his Qualification or Qualifications, to practise Medicine or Surgery, or Medicine and Surgery, as the Case may be, in any Part of Her Majesty's Dominions, and to demand and recover in any Court of Law, with full Costs of Suit, reasonable Charges for professional Aid, Advice, and Visits, and the Cost of any Medicines or other medical or surgical Appliances rendered or supplied by him to his Patients:" And whereas it is expedient to amend the said Enactment: Be it enacted by the Queen's most Excellent Majesty, by and with the Advice and Consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the Authority of the same, as follows:

1. This Act may be cited as "The Medical Act Amendment Act, 1868."

2. The Term "Colony" shall in this Act include all of Her Majesty's Possessions abroad in which there shall exist a Legislature as hereinafter defined, except the Channel Islands and the Isle of Man.

The Term "Colonial Legislature" shall signify the Authority, other than the Imperial Parliament or Her Majesty in Council, competent to make Laws for any Colony.

3. Every Colonial Legislature shall have full Power from Time to Time to make Laws for the Purpose of enforcing the Registration within its Jurisdiction of Persons who have been registered under "The Medical Act," anything in the said Act to the contrary notwithstanding: Provided, however, that any Person who has been duly registered under "The Medical Act" shall be entitled to be registered in any Colony, upon Payment of the Fees (if any) required for such Registration, and upon Proof, in such Manner as the said Colonial Legislature shall direct, of his Registration under the said Act.

NOTICE TO ADVERTISERS.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0	3s.	6d.
Per line afterwards	0	0s.	6d.
One-quarter page	1	0s.	0d.
Half „	1	15s.	0d.
One „	3	0s.	0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the Office, on Saturday, by Three o'Clock.

EXPORT OF THE CARLSBAD NATURAL MINERAL WATERS.

The wonderful natural properties of the Mineral Waters of Carlsbad are too well known to require commendation; they are a fact proved by the experience of many centuries. The waters can be used in the same way at home as at the Spring. The usual dose is One Bottle of Mineral Water each morning, taken at intervals of twenty minutes, either cold or warm, and after open-air exercise if practicable, or at home and in bed if necessary. To increase the aperient qualities of the bottled Carlsbad Waters, one teaspoonful of the Sprudel Salt should be added.

All orders for the MINERAL WATERS, SPRUDEL SALT, and SPRUDEL SOAP will be promptly executed at the Depots in all large towns, or direct by the Brunnen Nersendungs, direction of Heinrich Mattoni, Carlsbad, Bohemia.

LIQUOR OPII SEDATIVUS "HEATHFIELD'S" AS BATTLEY'S.

BEING Agents for this preparation, we beg to call the attention of the Medical Profession and of the Dispensing Chemists to its claims. It has been much prescribed by the Profession for many years, and we offer it with the greatest confidence as being prepared exactly on the same manner as Battley's. As a sedative the "Liquor Opii" has no equal, and as a favourite of forty years' standing it has maintained its position almost without a rival. We take this opportunity of urging its reputation and soliciting orders for same.

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION: THEIR DIAGNOSIS AND TREATMENT.

By S. SCOTT ALISON, M.D. EDIN.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

No. II

I NOW come to disease of the trachea and larynx and adjoining parts in their relation to pulmonary consumption as a simulator. This relation it is the great object of this paper to exhibit. Throat affections, when simulating pulmonary consumption, present that relation that is most interesting, inasmuch as they give rise to suspicion of dangerous disease that does not exist, constantly give way under skilful treatment, and carry away with them every fear of pulmonary mischief, or remain only for a time without impairing the value of life. These simulative diseases give scope to the exercise of that *examen eruditum* which enables the physician to declare with certainty the existence of only minor and generally curable disease, and the absence of a complaint most generally fatal. How useful and comforting this skill proves to the patient and to his friends, how valuable in many aspects—as, for instance, in relation to business affairs, to arrangements in domestic life, to travel, to place of residence, to life assurance, the value of annuities and reversions, and how pleasing it is to the physician, and how creditable to that art to which many are even now so prone to affix the stigma of incompetence.

That it is a common thing for purely throat affections to simulate chest disease, and more especially pulmonary consumption, I may safely say. Amongst some forty patients always under my care in the Brompton Hospital, I constantly have some who have, as far as I am able to judge, no disease whatever of the chest. During the eight years I have had the charge of in-patients, I have constantly had to record the absence of all pulmonary mischief, and the presence only of disorder of the trachea and other parts of the upper portion of the air-tube apparatus. These patients have been kept under observation in reasonable time to admit of further and repeated examination, and have not been dismissed until the most careful further scrutiny has confirmed the original diagnosis.

I have constantly had occasion to recommend the early dismissal of patients under such circumstances, and in no case have I heard that the dismissal turned out to be unfortunate—that is, was followed with evidence of disease of the chest. Such cases, it should be added, have been sent to the hospital as often as consumptive ones, and with medical certificates.

At present there are in the hospital under my care six patients with affections of the upper air-tube apparatus simulating more or less strongly pulmonary consumption; three are females and three are males. The chief morbid conditions are infected pharynx, enlarged tonsils, and congested condition of the trachea. The total number of patients is 43, and these six cases give a percentage of 16. The total number of pulmonary consumption cases is 26, and the six cases of simulated consumption with affections of the upper air-tube apparatus give the result of 23 per cent. to the cases of pulmonary consumption in the hospital under my care.

One of the most common forms of disorder of the trachea and other connected parts is a state of roseolar congestion of the trachea, larynx, and glottis, conjoined with nervous irritability and spasmodic action. Sometimes there is associated a general deterioration of the health and some loss of flesh. Sometimes the general health is good and the nutrition of the body is unimpaired, but in this latter case there is less likelihood of consumption of the lungs being successfully simulated. A condition of trachea giving rise to suspicion of tubercle of the lung, involving the form and calibre of the trachea, has frequently come under my notice, and I rather think has received little or no notice from pathologists. This condition is one of constriction or narrowing of the tube immediately above the bifurcation. The reduction of the calibre begins about an inch above the bifurcation, increases for half-an-inch, and then gradually reduces in the direction of the bifurcation. The extent to which the narrowing occurs varies, but is very manifest to the eye in many cases. The narrowing affects the whole circumference of the tube, and does not proceed from projections at particular spots. The cartilages remain of the normal length, the soft parts of the posterior wall only being reduced in breadth. This narrowing of the back wall devoid of cartilage is very obvious, and depends generally upon an undue amount of muscular contraction. No morbid lesions are found, saving narrowing and signs of over-vascularity and some thickening of the mucous membrane. When the measurements of the contracted part are compared with the calibre of the joint calibre of the two bronchi at the bifurcation they are found to be greatly deficient. The calibre of the narrowed part is also found unduly less than that of the trachea in its upper part. It should be mentioned that in health the trachea is narrower below than above, and the calibre of that part is less than the joint calibres of the two bronchi.

The excessive narrowing of the trachea gives rise to a certain continuous difficulty of respiration, great sense of oppression in the upper front part of the chest, including the region of the sternum. The difficulty is liable to exacerbations, an exposure of the patient to cold, and an occasion of increase of vascular congestion or of spasmodic action. This narrowing gives rise to difficulty in inspiration and also to difficulty in expiration. It is this condition of narrowing which so freqtently leads to emphysema of the lungs—a state occasionally associated with tubercle. The expiratory effort is opposed by the obstruction offered to the volume of air in course of expulsion, and the tender walls of the lung air-vesicles give way, dilate, coalesce, and give rise to wheezing lung inspiration, sibilant and sonorous rhonchi, imperfect oxygenation of the blood, in some cases purple countenance, and laboured and inefficient action of the heart, often accompanied with dilatation and softened flabby walls of that organ. The respiration through the trachea is highly noisy and constrictive, and this applies to the expiration as well as to the inspiration. The seat of the most intense constriction sound is immediately close to the sternum, where the stethoscope should be placed.

This morbidly narrowed condition of the trachea from its causing shortness of breath, serves to suggest the idea of consumption, and when it is associated with streaky hæmoptysis, which it sometimes is, with cough, general derangement of health, and loss of flesh, the idea of tubercle of the lung acquires strength with non-professional people, and even with medical men, who neglect the careful employment of auscultation and of other exploratory tests. The excessive shortness of breath in such cases, coupled with only moderate wasting of the body, the highly constricted respiration sounds in the throat, and the almost normal state of the respiratory voice, and percussion sounds of the chest, and of the shape and movements of that region, permits little doubt to rest in the mind of the practised physician as to the comparatively soft nature and generally local character of the disease, and as to the chance of tubercle in the lung.

It may serve to guard the young practitioner, however, to say here that such a narrowing of the trachea as has been described above, is sometimes associated as a sequela of tubercle of the lung, but exploration of the chest will easily establish this coincidence where it occurs.

In the healthy state, the trachea presents a difference in its volume at different parts. An inch above the bifurcation, on careful measurement of a healthy trachea, I found that a cord passed over the exterior measured three inches, while a cord passed round it immediately above the bifurcation, measured only two inches and seven-tenths.

The capacity of the trachea immediately above the bifurcation is greatly less than that of the conjoined capacities of the two bronchi at their origin. The internal circumference of the trachea at this spot, I found on careful examination of a normal organ, to be two inches and two-tenths, while the conjoined internal circumference of the two bronchi amounted to three inches and three-tenths.

The right bronchus exceeded in its internal circumference the left by one-tenth of an inch.

Stricture and constriction of the trachea have been referred to in various works on the throat, but their morbid conditions, as there described, have been more restricting and partial than the constricted condition of the trachea which I have endeavoured to describe. The partially constricted condition of the trachea, which points from tumours and foreign bodies *in* the tube, and from tumours *outside*, and from injuries by violence, are, of course, altogether distinct from the narrowing of the trachea, which I have desired to bring under the notice of the reader.

Hypertrophy and engorgement of the mucous follicles of the posterior wall of the pharynx have been, in some cases of suspected pulmonary consumption, the only pathological conditions discernable under the most careful and repeated exploration. The posterior wall has been seen roughened and unduly injected, presenting an unusually florid colour, or an undue clarety aspect, together with enlarged and various venous twigs.

The uvula, in some few examples, has been the only structure that has presented a morbid condition ; generally it has been injected, often it has been hypertrophied ; sometimes, on the other hand, it has been greatly reduced in size, or totally obliterated, but this part has often been found unduly long, occasionally clubbed at its extremity, but more frequently tapering to rather a fine point, membranous and almost transparent.

The tonsils, in numerous examples of merely simulated pulmonary consumption, have been the only parts which, under diligent and repeated examinations, have presented a morbid condition. The morbid condition has varied, but in most examples it has been one of considerable enlargement, undue redness and vascularity, with mucous depressions, as if scarred, or chopped, or pock-pitted. This state has usually been shared by both tonsils, but occasionally it has been confined to one. When both tonsils have been enlarged to the size of walnuts, they have, by approaching each other, greatly contracted the entrance into the pharynx, and interfered with the free pendency of the uvula. In such cases the voice has had an unduly nasal tone, and some little difficulty has been experienced in swallowing. The respiration through the trachea in most cases has been highly constrictive, and I have observed in a majority of the patients a sensible amount of hardness of hearing.

That cases such as the above are sometimes treated as examples of pulmonary consumption, there is no doubt whatever. The cough, the occasional streak of blood, and the impediment to free perspiration, suffice to this end. Such cases of simulated pulmonary consumption are common in children, and in young persons about puberty.

A girl about 12 years of age came into the Rose ward lately with such a condition of tonsils as has been described. She was rather plump. No sign of tubercle of the lung being made out, I enquired more particularly into her history. She had come to the hospital from a place in the country many miles from town, and she informed me she had seen (I believe) some eleven doctors. It was clearly a case for surgical aid, and Sir W. Fergusson, the surgeon to the hospital, being sent for, removed the hypertrophied parts, and the patient was then sent home, carrying with her no signs whatever of chest disease recognizable by myself, the house-surgeon, or my clinical assistant.

NOTES ON SOME PECULIAR CASES OF SYPHILIS.

By ANGUS M. PORTER, M.D.

(Continued from page 26.)

CASE 3rd necessarily includes two parties—husband and wife.

On January 11, 1868, Mr. D. came to get advice for what appeared to be herpes preputialis. He said he had been treated for the same affection some three years before, and that the late Dr. Halliday cured him in a very short time. He remembered the name *herpes* to have been used by Dr. Halliday on that occasion. The gentleman's regular habits, and unimpeached character, seemed to place him beyond suspicion of impurity of mind or body, still great caution was required in answering his pointed questions, as he seemed in greater dread of the disease than its condition at the time warranted, or his past experience should have admitted of. Considering that the patient should be prepared for the possibility of evil consequences, I reserved judgment, and suggested the likelihood of his having contracted the disease in a foul privy, which hint he willingly accepted, as furnishing a respectable *fons et origo mali*.

He had been away on business in the south of Ireland, and two days before coming to me he first noticed *itching* of the prepuce. He was a most temperate and regular man, as already mentioned, and lived happily with his wife (who at this time was about seven months pregnant).

Rest, repeated bathings, the application of dilute lead lotion, and a mild purgative, were the remedies advised.

On January 14th he was quite free from the local disease, no irritation whatever remaining, but nocturnal perspirations had become a great source of discomfort to him; for this he was recommended to sponge with tepid water impregnated with sulphuric acid.

He returned on February 4, suffering from marked febrile symptoms (hot dry skin, headache, constipation, and quick pulse). For two days he had observed a bright scarlet rash (roseola) to come and go on his chest and abdomen. On examination the glandulæ concatinatæ were found enlarged, copper-coloured stains were discovered at the flexure of his right elbow and the back of his neck, his forehead had become very rough, but not discoloured. His throat was simply erythematous. The glands of each groin remained unaffected.

Corrosive sublimate in compound infusion of gentian, to be taken with cod-liver oil, as in case 2, also 15 grs. of Dover's powder each night, rest, and plain nourishing diet constituted the treatment at this stage of his illness. He was recommended strong alum water gargle for his throat.

Eleven days later (February 15), on visiting Mr. D. at his own house, I was glad to see that a great improvement had taken place in his health. The cutaneous disorders were dying away; his throat was much better with the exception of a small ulcer which had attacked the left tonsil. The glands at the back of his neck were not so perceptible, and the stains mentioned before were not so distinct. He stated that he had derived considerable benefit from sponging with the acidulated water. He complained now of his eyes being rather sore, and his sight weak, but I could not detect any morbid appearances.

His wife had now unfortunately become a sharer in his sorrow, and evidently a partaker of the forbidden fruit. Her chest was as red as the shell of a boiled lobster; the glandulæ concatinatæ greatly enlarged, and the throat very sore, but not ulcerated. She was depressed in spirits, and feverish. She readily submitted to an examination, when for the first time she became aware of a number of ragged ulcers on the mucous surfaces of the labia. To the inside of each thigh was a patch of vesicles, which were highly inflamed and intensely itchy. A thick row of pustules extended up from the fundament to the end of the coccyx. There was no tenderness in either groin, nor could any hardness be felt, the chancres, also, were free from induration.

After cauterizing all the chancres with nitric acid, and the pustules and vesicles with nitrate of silver, the parts were all stuped with poppy-head water, then dilute lead lotion on lint covered with gutta-percha tissue was applied, and the patient kept in bed. The internal medicines consisted of iodide of potassium in six grain doses, with three drachms of fluid extract of sarsaparilla in water, three times daily; ten grains of Dover's powder occasionally at bed time, and full doses of liquid extract of senna, as an aperient, when required. For the throat a powerful astringent gargle was ordered, containing tannic and the mineral acids.

February 18th.—Some superficial ulcers which had formed on the tonsils were burnt with lunar caustic. Calomel was dusted on the vulva and perinæum.

On the 23rd inst., considerable improvement had taken place, both locally and general. The calomel seemed to have thoroughly withered up the pustules, and the condition of the chancres had so far improved, as that no [illegible] was experienced. The throat was again touched with nitrate of silver, and the other remedies continued.

On March 14th, Mr. D.——, who had been away on business, and persevering with the prescribed treatment, returned, complaining of severe rheumatism in his right arm, which he could not bend nor raise to his head. Febrile disturbance, ulceration of the tonsils, weakness of sight, and falling out of his hair, were the accompanying symptoms. He was now recommended Donovan's solution, and stimulating applications to the hair, as in Case 2. The following liniment greatly relieved the pain in his arm:—

℞ Lin. aconiti.
— Bellad.
— Chloroform.
— Opii aa. ʒss.
— Camph., co. ℥ii. M.
Ft. linim.

The ulcers on his tonsils were being daily brushed with a strong solution of nitrate of silver, and thereby improved rapidly. Two days later (March 17) Mrs. D.'s right arm became affected in precisely the same way as her husband's, when the same embrocation as was used in his case proved equally efficacious in the removal of pain.

In the course of a week both parties were perfectly free from this latter symptom.

Both patients continued to improve from this forward, save as regarded the ulcers of the throat, which in each case seemed difficult of cure.

On April 14, a bald ulcer appeared on the right side of Mrs. D.'s tongue, for which she was recommended chlorate of potass in ten gr. doses, as was also her husband.

23rd.—The lady was confined of a very fine healthy son, free from any mark of disease or delicacy. For it she had a plentiful supply of milk, of which it partook freely.

Her mouth and throat had quite returned to a normal state. All remedies were now dispensed with, it being considered unnecessary to further continue their use.

Mr. D., who had been travelling on business from the preceding Saturday, arrived home on April 25th, and, I may say, almost recovered. His hair had ceased to fall out. No cutaneous eruption whatever remained, but the throat was still slightly troublesome, and his sight still impaired. I ordered him a strengthening eye-wash, and told him to continue the chlorate of potass and the oil, which he did till the end of the month, when, being apparently cured, he left off taking anything in the shape of medicine.

In this last case, or joint case as it may be termed, the first peculiarity noticed was the herpetic character of the primary disease, and the rapidity with which it was cured, contrary to the law of specific sores; secondly, the occurrence of night perspirations (generally looked on as a late symptom of constitutional syphilis) five days after the first appearance of local disease, or as soon as the latter was removed; thirdly, the development seventeen days later of secondaries (roseola, copper-coloured stains, and erythema of throat), the lymphatic ganglia of the groin remaining unaffected. Fourthly, the presence of vesicles in the lady's case on the inner surface of each thigh, precisely similar to those which were observed on the prepuce of her husband, and the absence, as with him, of glandular enlargement in either groin. Fifthly, the almost simultaneous attack of rheumatism in the two persons; and, lastly, the equally satisfactory results which attended the treatment of the one by iodine and the other by mercury; and the untainted condition of their infant when born.

THREE CASES OF MITRAL DISEASE, IN WHICH THERE WERE NO MURMURS ON ACCOUNT OF THE INTENSITY OF THE VALVULAR LESION.

By LAWSON TAIT.

In the summer of 1866 I placed a young Irishman under the care of my much-lamented friend, the late Dr. Scoresby-

Jackson. The patient was about twenty-four years of age, and suffered from rheumatic fever about five years previous to the time I first saw him. The history of his illness pointed to pericarditis as the lesion from which he had suffered; but no very definite history could be obtained.

The appearance presented by him was not very much that of a man suffering from heart-disease. He was breathless in going up a hill, complained of uneasiness over his heart, and great weakness. At first sight I took his case to be one of phthisis; but examination did not give any reason to support this. The action of the heart was irregular, or rather every now and then there occurred an interval of rather greater length than a beat, during which the heart seemed to be still, and then there was very markedly that vermicular motion under the skin supposed to indicate adherent pericardium. The latter, indeed, was the condition that I diagnosed; and Dr. Jackson agreed that this probably was the case. The patient was examined by several competent stethoscopists, and while several concurred with us, none, if I remember rightly, suggested mitral disease. The patient left hospital, and died in three weeks. After a very great deal of trouble I got permission to examine the condition of the heart, and found, very much to my surprise, not only that the pericardium was not adherent, but that, with the exception of a few milk-spots, it was perfectly healthy. The heart was considerably hypertrophied. The mitral valve admitted only the forefinger, and was perfectly rigid, being, in fact, only a ring of calcareous matter, from which the endocardium on the upper side had been denuded by ulceration. Many of the *chordeæ tendineæ* were ruptured, or had been ulcerated through.

J. G., æt. 37, had never suffered from any form of rheumatism, but for the last five years had suffered from symptoms which led his medical attendant to believe that he had some form of disease of the heart. He presented an extremely anæmic appearance, had some general symptoms, such as slight cough, occasional bloody sputism, breathlessness on exertion; but there was no murmur, only the same irregular and tumultuous action of the heart. I had no means of registering the heart's action, but it might be roughly represented thus, taking the period from the beginning of one beat to the beginning of another as 5:—

5 : 5 : 12 : 5 : 3 : 3 : 5 : 5 : 12 :

From the above conditions I suggested mitral disease as the cause of his symptoms, and ventured to diagnose a condition similar to the case first mentioned. He died in a few months, and I found my diagnosis most singularly well established; the mitral orifice would not admit the fore-finger, and it only wanted an extension of the deposit for an eighth of an inch at one spot to make it a complete circle of cretaceous material. The endocardium seemed to be still intact over the foreign substance. The heart was considerably hypertrophied. As both the above examinations had to be conducted hurriedly in private houses, with friends of the deceased looking on, weights and measurements could not be more accurately taken.

A. P., æt. 29, presented an extremely anæmic condition. A year before I saw her, she had her right breast removed for malignant disease, in St. Mary's Hospital, Manchester. For some months after her recovery she acted as a barmaid, and enjoyed fair health. About seven months after the operation she found that on any unusual exertion she became breathless, and this increased so rapidly, that in two months more she had to give up work. Her condition, when I saw her, indicated serious disease; and from the physical signs being identical with those of the second case, I diagnosed mitral constriction with inelasticity of the valvular appendages. The question came up—Might it be malignant disease? and I was inclined to believe that it was. The fatal issue occurred three weeks after she came under my care, and post-mortem examination showed that I was right as to the condition of the valve, but wrong as to the disease. The valve admitted the middle-finger, and both flaps were much ulcerated on the upper surface. The disease was ordinary atheroma, softer, however, than in the other two cases, and extended completely round the orifice. The aortic valve had only two segments, and the pericardium was congenitally absent.

That the intensity of the murmur has no general relationship to the amount of lesion, and that many very serious forms of heart affection are entirely without murmur, are facts well understood and frequently insisted on; but that the murmur in valvular affections may be in abeyance from the very intensity of the disease, is a condition not so generally recognised.

SHORT NOTES ON NICE.

By JAMES STANNUS HUGHES, M.D., F.R.C.S.I.,
PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS, IRELAND; SURGEON TO JERVIS-STREET HOSPITAL; CONSULTING SURGEON TO THE COOMBE LYING-IN HOSPITAL; SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD, ETC.

No. III.

SOME of the best published observations I have read on the climate of Nice are the following, which are contained in that excellent little work of Dr. Edwin Lee's, which he has published under the heading of "Nice and its Climate," a book I can strongly recommend to those about to visit Nice, viz.:—

"The frequentation of Nice and its environs on the score of health dates from the period of the occupation of the country by the Romans, when patients were frequently sent from Rome to Cimiez; and the reputation of this climate has ever since been maintained; many professional and non-professional writers having spoken highly in its favour. About 100 years ago, Smollett observed in his 'Letters from Nice,' 'There is no place where rain and wind prevail less (in winter) than here. To give you an idea of the serenity of the air, I can assure you that during whole months one sees above one's head nothing but a deep blue. The air being pure, dry, and elastic, must exercise a salutary influence upon the constitution of persons affected with diseases of the nervous system; it must also be suited to those who suffer from checked perspiration, from relaxed fibres, and a tendency to languors. For my part, since I have installed myself here, I breathe more freely than I had done for several years before, and I feel myself transported with a vivacity previously unknown to me. The Nice air has likewise relieved me from a slow fever, which had resisted every treatment and had rendered life an intolerable burden to me. I do not take cold here so easily as in France or in England; when I do, it is not attended with the same serious symptoms as in other countries. The air is so perfectly dry that in summer and in winter one may pass the evening, and even the night, *sub dio*, without experiencing inconvenience, or feeling the least moisture. Fog is here altogether unknown.'

"A German physician, Dr. Sulzer, likewise wrote at a later period (1792): 'I cannot quit this country without panegyrising its climate, which is excellent among the most privileged. The English who are accustomed to leave their cloudy island in autumn to pass the winter in the southern zones of Europe, have greatly contributed to bring into repute the remedial and comforting influence of the environs of Nice, and assuredly this reputation is well merited in more respects than one. Persons who do not look for the noisy pleasures of large capitals are sure of finding here a benignant and constantly warm atmosphere in which the body feels its infirmities disperse, and its youth regained. Here, one is sheltered from cold, snow, and fog, and one enjoys in the depth of winter the delights of a perpetual spring.

"'The air of Nice seems to me to be much more pure and serene than anywhere else. A tolerable judgment may be formed of its character in this respect from the brightness and sparkling of the constellations, and the number of shooting stars, which are only visible in Germany on the finest winter nights. There is, perhaps, no town in Europe which is so well adapted for the establishment of an observatory; for even in rainy weather, one does not perceive that the air becomes saturated with humidity, or that it is thick. Hence, an invalid who wants to breathe a pure and dry air, and to take exercise, will find at Nice all that can hasten his restoration. The promenade around the town is really very agreeable, though rather short; but those who like variety should make excursions among the valleys and on the hills, where the beauty and the variety of the points of view are inexhaustible. In this privileged climate nature does not repose during winter; the gardens retain their green foliage, and spring flowers are constantly seen. The uncultivated places on the mountains are perpetually clothed with grasses; the plains are embellished with flowers and trees bearing blossoms and fruits, among which the orange and lemon trees display a brightness of colouring that is remarkable at such a time of the year.'

"A more recent author (Foderé) remarks respecting the district: 'Six leagues of the coast constitute the maritime portion of this country, and comprise the towns of Nice, Villefranche, Monaco, and Menton; as also the villages of Eza, Turbia, and Roqueburne, which are placed on rocks bordering the sea. This territory is remarkable for its olive woods, its carob trees, and especially for its orange and lemon trees, which, being always green, and laden with fruit and flowers, present to the traveller the aspect of perpetual spring.

"'The mountainous part of the district, which is the most extensive, differs in its productions according to its eastern, southern, northern, or western exposure. In the former all the successive chains of mountains, rising higher and higher, which close the horizon of this maritime coast, produce the vine and olive at their base and on their sides; their summits being bare. From all the more elevated points of these mountains, at a distance of four, five, and six leagues from the coast, the sea is visible, and from all these points the warm and soft breath of the south and east winds blow. On their opposite side the north wind prevails, and the country produces only wheat and barley. One is really surprised to find, frequently in two villages at a very short distance from each other, productions of an entirely different nature. The lower chain of these Alps is the most populous and the most fertile. It comprises the villages of Falicon, St. André, Tourette, Aspremonte, Contes, Chateauneuf, and Levens, to the right of Nice; on its left those of Drap and Scarena.

"'The beauty and serenity of the atmosphere, and an always reviving nature, add fresh charms to that of the mild temperature. Nowhere on the fine days of autumn and winter is the sky of a purer blue, or more cloudless, than in lower Provence; we begin to admire it on descending the Rhone, after passing Valence; it is like the sky of Greece, and Provence is the Greece of the Gauls.'[1]

"The above eulogiums are likewise in some measure applicable to other localities which were not known at the time they were penned; and, notwithstanding the flattering picture they present, it must not be supposed that Nice is exempted from some material drawbacks to its enjoyment as a place of winter abode.

"Even Smollett, who speaks in such high terms of the climate in general, remarks with respect to the transitions of temperature that are frequently experienced: 'It often happens in winter, and especially in spring, that the sun has so much power that one can hardly take exercise without its producing sweating, and without any transition the wind arises so cold and piercing that it is liable to produce a very dangerous effect, and diseases with an inflammatory complication may result from this sudden change.'

"'Heaven forbid' likewise says a native writer, 'that we should seek to conceal any of the inconveniences of the place; the inconstancy of the winds is extreme; they frequently change several times a-day. It likewise sometimes happens that several winds blow strongly at the same time; an ærial tempest ensues, and then this fine climate changes from hot to cold, and *vice versa*. These changes sometimes occasion, especially in spring, such an unexpected return of cold weather, that if there is no winter at Nice, it may also be said there is no spring; in fact, the winter is so mild, and the spring comes in so quickly, that unless the course of these seasons be interverted by stormy winds, the transition from winter to summer is scarcely perceived.'[1]

"All this sheltered part of the Mediterranean coast presents, however, in my opinion, more advantages and fewer drawbacks as respects climate, and is more applicable to a large class of invalids from northern countries than most other places of winter resort; and I am desirous, in corroboration of this opinion, to show the estimation in which it is held by medical and non-medical authors who are not residents, and whose opinions may, therefore, be considered as exempt from local bias. The following favourable notice is taken from a small work already quoted: 'I have no hesitation in saying,' writes Mr. Dunbar, 'that by most persons, whether in invalid or in robust health, Nice must be considered a most desirable and agreeable place in which to spend the coldest months of the year. Of course the climate has its peculiarities, which are found to suit some complaints and some constitutions better than others.

"'But apart from such specialities, if any one seeks a mild yet dry and invigorating atmosphere, an almost invariably bright and serene sky, giving a cheerfulness of aspect to all things without, and tending to communicate itself to the mind within; if it be desired to avoid the extreme of cold, or even the ordinary gloom and severity of our northern winter, then I can confidently recommend a winter at Nice. If my opinion on such a matter is worth anything, it ought to be regarded as a testimony all the more favourable to Nice, from the fact, that my impression of it has been formed during a season somewhat exceptional for its changeableness even here, and acknowledged to have been the most severe and inclement that has visited other parts of Europe for many years. My own register of the thermometer, and observation of the weather generally, during the last few months, show a degree of mildness and steadiness of temperature, not to be surpassed probably in any other locality in Europe. This I find to be fully borne out by meteorological tables, kept by residents here for a series of past years.

"'It is not, however, to be inferred that the climate of Nice is free from all disagreeable changes or drawbacks. There are quite sufficient of these to make unreasonable grumblers occasionally announce their disappointment that the weather is not every day and every hour entirely perfect. After several weeks, perhaps, of steady mildness and clear skies, a day or two of clouds will occur, and forthwith you hear, 'Is this your boasted climate? Why it is no better than a November day in London.' A chilly morning or a cold wind displeases them. 'It could not be much colder in England,' forgetting that while the prevalence of fine weather may be reckoned by weeks, the reverse is a matter only of days. For my own part, I can bear this testimony to the credit of the climate: that, with the exception of a few days of chilly rain and sleet in the middle of December, and two or three sharp frosty mornings about Christmas, I have seen nothing this season that at all realizes our idea of winter. January was a month of uninterrupted mildness and even warmth of temperature, the sky always serene, for the most part cloudless, and marked by a singular absence of wind, or any disturbing influence; the frosty mornings above alluded to occurred, be it observed, when all the more northern parts of Europe were benumbed and paralyzed by an intensity of cold, such as will make the December of 1860 memorable for generations to come.

"'From a series of tables extending over seven years, I observe that the thremometer did not fall as low as the freezing point more than two or at most three times during the winter, and that it never reached lower than 28. These observations were taken in a northern exposure, and in the shade. The number of days characterized throughout by clear sunshine have been reckoned at 180 in the year, divided as follows: winter 42, spring 42, autumn 40, summer 56; the remaining 185 days include those that are dry and fine though cloudy (which occur principally in autumn and in the first winter months); those that are showery, and those that are regularly wet. Another most agreeable and, to the invalid, most valuable feature of the climate, is the remarkable number of calm days during the winter. Blustering winds, so fatiguing to the body, and so trying to the organs of respiration, are here but seldom experienced (through November, December, and great part of January). Even when the air is sharp, and comparatively cold in the morning, its undisturbed stillness, combined with its elastic dryness, render the early part of the day peculiarly pleasant and invigorating for out-door exercise. The March winds, with their cloud of dust, though undoubtedly the drawback of Nice in the latter part of the winter season, are, in my experience at least, neither so frequent nor so formidable as they are often represented.'

---

[1] "Voyage aux Alpes Maritimes."

[1] Roubaudi.—"Nice et ses Environs."

"As regards the effect of the climate, after adverting to the benefit derived by patients 'in numerous cases of general delicacy, or temporary derangement of health, arising from a feeble organization, a sluggish state of the circulation or secretions, resulting in a low nervous tone, physical and mental,' this author adds, 'I have known several cases, among the many that continually occur, of feeble, delicate children having been brought to Nice in a condition in which it seemed as though a few weeks or months must terminate their existence, but on whom the invigorating air and sunshine of this place has proved like a new life breathed upon them, causing their little frames to vegetate with a strength and vigour almost from day to day.

"'Common sense will at once perceive that a climate with properties so strongly marked must be unsuitable to some persons, and some stages of disease, just from the very causes that make it beneficial to others. But, if I may form any opinion from the number and variety of cases and complaints among the visitors I have known and heard of here this season, and the effects their sojourn at Nice has produced upon them, I am inclined to think that such exceptional cases are much fewer than are generally supposed.'[1]

(To be continued.)

Hospital Reports.

RICHMOND SURGICAL HOSPITAL.

CASES UNDER THE CARE OF MR. WILLIAM STOKES.

(Reported by Mr. JAMES CRAWFORD.)

EXCISION OF THE UPPER JAW.

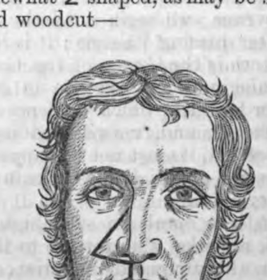
THIS operation, which, although one of modern date, Mr. Lizars, of Edinburgh, in 1826, having been the first to propose the entire resection of the bone, and, as we learn in the exhaustive chapter on the subject in Mr. Butcher's "Operative and Conservative Surgery," was first performed by M. Gensoul, surgeon to the Hotel Dieu, at Lyons, in 1827, is one, which, though very rarely performed, has associated with it the names of many of the most illustrious surgeons of the Irish, British, and Continental schools of surgery. Not to particularise any of the eminent living surgeons who have performed, and truthfully recorded the results of their experience of this great operation, the names of Cusack, Liston, Dupuytren, Lizars, Gensoul, Mott, Velpeau, Dieffenbach, and Lisfranc, may, in truth, be mentioned. As it would be out of place in an hospital report to enter into particulars in reference to any historical details connected with this operation, we may proceed at once to detail with brevity the particulars of a case which was recently under observation in Mr. Stokes' wards, in the Richmond Hospital, and for which the operation of excision of the upper jaw was performed by him.

James M., æt. 50, was admitted into the Richmond Hospital on the 1st of last March, having been recommended to Mr. Stokes by his colleague, Dr. Lyons.

The patient stated that about a year before the date of his admission into hospital a small ulceration appeared at the junction of the soft and hard palates. This ulceration, which presented all the external characters of epithelioma, was removed by operation last September. After some time, however, the disease returned, and spread slowly, both anteriorly and posteriorly. It never extended, however, beyond the mesial line. About a month before the patient's admission into hospital the disease appeared externally, on the cheek namely, and from this opening there was a constant oozing of clear fluid, which, as the opening was in the immediate vicinity of Steno's duct, was most probably saliva. The general health of the patient was excellent, and there was only one small gland which was perceptibly enlarged, and which was situated immediately below the angle of the jaw. The epithelial ulceration, which was very irregular, extended considerably both in front of and behind the junction of the soft and hard palate. There was occasional but very slight hæmorrhage from the ulceration. The patient slept well, and his appetite was excellent.

Having regard as well to the external characters of the disease as to its clinical history, it was tolerably evident that the case was one of epithelioma, which had originated in the muco-periosteum of the hard palate, and which subsequently involved the bone to a considerable extent. Although, doubtless, the case could not be considered a typical one for the operation of resection, permanent benefit, as Professor Syme observes, being in all cases more confidently to be expected from the operation, when the consistence of the tumour is essentially firm, yet, considering the comparatively limited extent of the disease, the case was, in Mr. Stokes', and also in Professor Adams', opinion, one that demanded prompt operative interference.

On March 4th the patient was brought into the operating theatre, and placed seated in a strong and high-backed chair. His arms and legs having been carefully secured by bandages to the chair, chloroform was then administered. When the patient was brought fully under its influence, Mr. Stokes commenced by making an incision from the inner angle of the eye downwards and outwards to the inner edge of the salivary fistula. The incision was then carried horizontally inwards towards the mesial line, near the septum of the nose, and finally brought vertically downwards, a little to the right of the central line, through the red border of the lip. The incision thus made was, therefore, somewhat Z shaped, as may be seen by reference to the annexed woodcut—



Mr. Stokes' Incision for Resection of the Upper Jaw.

The inner flap, or that next the nose, was dissected carefully backwards towards the left side, and then the two superior maxillary bones were separated by Charrière's long bone forceps, one limb of this powerful instrument being placed along the floor of the nose, and the other in the mouth. The separation of these bones was effected by this admirable instrument with the utmost facility. The posterior flap was then dissected backwards towards the arch of the zygoma. At the junction of the superior maxillary bone with the malar, the separation was effectually accomplished by one of Langenbeck's small resection saws. When this was done the saw was then carried upwards and inwards, below the infra-orbital ridge, up to the junction of the nasal bone with the nasal process of the superior maxillary bone. Great care was taken not to interfere with the floor of the orbit. The necessary division of the osseous structures having been now accomplished, the separated bone was seized with one of Sir William Fergusson's lion forceps, and without much difficulty was removed. Other portions of bone which were found to be diseased were carefully removed by straight and rectangular gouges, and the horizontal plate of the palate bone was also removed by strong forceps; portion of the soft palate on the right side was also excised by strong curved scissors. The hæmorrhage was not at all so great as was anticipated. Only one vessel had to be ligatured. Any hæmorrhage from others, was effectually arrested by the free application of the actual cautery. No plugs of lint or any dressings were placed in the cavity. The edges of the wound were then brought together by numerous metallic points of suture.

---

[1] "From London to Nice, 1861."—Hamilton, Adams, and Co. See also the Addenda.

As regards the progress of this case, little that is specially remarkable is to be observed. No secondary hæmorrhage occurred. Two days after the operation, symptoms of erysipelas of the head developed themselves, commencing on the bridge of the nose. However, under the use of antimonials and mild purgatives, &c., they subsided. The wound in the face healed with surprising rapidity. Four of the sutures were removed on the third day, and the remainder on the fifth. The case progressed in every way most favourably. On the tenth day after the operation the following note is in Mr. Stokes' case-book :—"The patient is free from all pain and uneasiness. Eats, drinks, and sleeps well. His articulation is becoming more distinct every day. There is no evidence of the reformation of a salivary fistula."

On March 23, exactly nineteen days after the operation, the patient was photographed by Mr. Foster, of Westmoreland-street, and on the following day he returned to the country.

CITY OF DUBLIN HOSPITAL.

SURGICAL CASES UNDER THE CARE OF MR. CROLY.

Case 1.—DOUBLE ANTHRAX ON THE ABDOMEN.

G. W., aged 60 years, of bilious temperament, and previously healthy, presented himself amongst the extern patients, suffering from well-marked double Anthrax, situated on the upper third of the right rectus abdominis muscle. He said they commenced as pimples about ten days previously, and gradually spread. He has suffered from burning pain in the part, and slept very badly for several nights. The tumours are situated near each other with an inch of sound integument intervening. Each Anthrax measures three and a-half inches by two and a-half; they are flat, and a number of small openings have formed on the surfaces; more pain than usual is felt, in consequence of the action of the rectus muscle.

Treatment.—Mr. Croly proceeded to strap each Anthrax separately as follows—half-moon shaped strips of *soap* plaster were evenly applied above and below the Anthrax, commencing at the circumference, and overlapping each other, a small circular opening being left in the centre to allow the slough to escape. When the strapping was completed the patient said he felt immediate relief from the pain. Quinine, with chlorate of potash, was prescribed in mixture, and the patient was directed to live well, which his circumstances admitted of. Carbolic acid ointment was applied on lint over the central portion of the Anthrax during the day, and an emollient poultice was directed to be applied at night. The patient continued to attend as an extern patient, and the strapping was regularly renewed; the dead areolar-tissue became detached gradually, and finally the ulcerated surface healed by granulation.

A drawing of this rare case of double Anthrax on the abdomen, was taken by Mr. Burnside.

Case 2.—SINGLE ANTHRAX ON THE ABDOMEN.

T. M., aged 43 years, a cooper by trade, presented himself as an extern patient with an Anthrax in circumference the size of a small orange, situated on the upper third of the right rectus abdominis muscle. He noticed a small pimple some days previously, it gradually increased in size; he fancied the "bit and brace," with which he worked, was the cause of the disease. He did not sleep for several nights, and suffered severe pain of a burning character. The Anthrax was flat, and a number of small openings had formed on its surface. The same mode of treatment was adopted as in the preceding case—viz., strapping with *soap* plaster and tonic medicines, with liberal diet. This case also recovered quickly.

Mr. Croly made some practical observations on these cases—he alluded to the comparative rarity of Anthrax on the abdomen (especially when double), and the extreme pain produced by the disease when situated in that region, caused by the action of the rectus muscle; he also mentioned Dupuytren's opinion regarding the sloughing of the subcutaneous areolar-tissue in Anthrax, and the more modern view of Nélaton, who believes the so-called slough to be a false membrane, analogous to that formed in croup and diphtheria. The treatment by strapping in these cases afforded instant relief (probably by fixing that portion of the muscle on which the tumours were situated), and the mode of applying the plaster in half circles, adopted by Mr. Croly, was very satisfactory. The names of Nélaton and O'Ferrall were mentioned as the earliest adopters of strapping in cases of Anthrax, with a view of supporting the capillaries and hastening the discharge of the slough or false membrane. Mr. Croly tested the urine in both these cases, but did not discover any saccharine matter, which probably is never present except when Anthrax occurs in diabetic patients. Mr. Croly added that the treatment by crucial incisions (the long approved practice for Anthrax) is now becoming obsolete, except in some special cases; incisions are not only very painful but produce considerable shock, acting on constitutions already debilitated.

Case 3.—NOMA PUDENDI.

A. E., a delicate, anæmic-looking child, was presented amongst the extern patients. Her mother states she noticed a scalded appearance between the right labium and thigh some days previously; the part became swollen and painful; the child perspired at night and lost all appetite for food. On examination, a large oval black slough was observed occupying the right labium; there was much fœtor from the slough.

Treatment.—The part having been dried with lint, Mr. Croly applied the strong nitric acid to the diseased surface, and prescribed chlorate of potash in syrup of bark. A liberal supply of wine and beef-tea was also directed to be given. The acid was applied on several occasions subsequently as the disease was inclined to spread; the case ultimately recovered well.

PAUPERISM—The annual New Year's-day return of persons in relief from the rates in England and Wales shows that on the 1st of January, 1868, the number was 1,040,103, being an increase of 76,903, or 8 per cent. over the number on the 1st of January, 1867. The proportion of paupers at the beginning of 1868 was therefore one in 19, or 5·2 per cent. of the actual population. New Year's-day being in the depth of winter is, of course, a time when the number of paupers is large; and the numbers stated are about 1 per cent. lower than the truth, by reason of deficient returns. The adult able-bodied paupers, 185,630, were 27,822 (17·3 per cent.) more than on the 1st of January, 1867; 53,487 were men, 132,143 women. The whole number of adults receiving relief (including 42,026 insane persons), were 220,097 men and 434,042 women. 6129 vagrants were also receiving relief, but among these the adults are not distinguished.

GENERAL MEDICAL COUNCIL.

The following Returns were received and entered on the Minutes of the GENERAL MEDICAL COUNCIL, at the ANNUAL MEETING held on the 24th of June, 1868 :—

STATEMENT OF THE QUALIFICATIONS OF THE CANDIDATES FOR THE MEDICAL DEPARTMENT OF THE ARMY, WHO IN AUGUST, 1867, PRESENTED THEMSELVES FOR EXAMINATION.

NAMES OF LICENSING BODIES.		QUALIFICATIONS. Number of Qualifications. Total.	No. Passed.	No. Failed.	Deficient in Anatomy.	Surgery.	Medicine.	Operations.	All Subjects.
Roy. Col. of Phys., Lon.,	Lic.	1	1	...	...	...	...	...	...

Total number of Qualifications		113	97	16	14	4	8	10	4

REMARKS.

Candidates.—Successful, 44 ; failed, 8. Total, 52.

Two of the candidates had each four qualifications, and five of the candidates had each three qualifications, which adds nine to the required number of qualifications (two each) of the fifty-two candidates.

Eight of the passed candidates were deficient in one subject each, but not to such an extent as to necessitate their rejection.

Diplomas and Degrees.—Successful, 26 ; failed, 8. Total, 34.

N.B.—1. Two of the candidates had a third qualification.

2. Of the four candidates returned as successful, three were qualified, but were not accepted, as only twelve appointments were to be made.

THE annual meeting of the Northern Branch of the British Medical Association was held at Darlington, under the presidency of Dr. Charlton, on Wednesday, July 1st. The next gathering will be at Newcastle, the president-elect being Dr. Embleton. In the evening the members dined together, Mr. Jobson, the new president, in the chair. Dr. Phillipson occupied the vice-chair.

Obituary Notices.

DR. KENNION.

On the night of June 30th, there died at his residence, Oak Lea, Harrogate, Dr. George Kennion, F.R.C.P. Lond., well-known for many years as an active and prosperous Physician by all who were at all familiar with Harrogate and its famous waters.

Dr. Kennion's father was rector of Christ Church, High Harrogate, and removed thither from the vicinity of London when the late Doctor was only twelve years of age. After studying physic both in London and Edinburgh, Dr. Kennion commenced practice at Harrogate in 1840 as successor to Dr. Richardson. He gradually and steadily rose to eminence, so that of late years a large number of the highest classes of the community resorted to Harrogate for the sake of his advice, and during the season, between the hours of twelve and two, there was always a vast concourse of people waiting to consult the Doctor on his return from his morning round of visits.

Dr. Kennion did much towards promoting the proper and judicious use of the Harrogate waters.

The Kissengen Spring in Montpelier Gardens, which has of late years become so famous, owes very much of its popularity to Dr. Kennion, and he, in conjunction with Dr. Sheridan Muspratt, brought also into prominent notice the Protochloride of Iron Spring, one of the strongest and most powerful chalybeates to be found anywhere on the globe.

Dr. Kennion's small work on the "Medicinal Springs of Harrogate," now in its sixth edition, is well-known probably to most of our readers.

While endeavouring thus to speak of Dr. Kennion's well-earned fame as a scientific and skilful physician, we shall be doing him scant justice if we omit to speak of him as a kind and most hospitable gentleman, and as a true and liberal-minded Christian. In his busiest time, when working hard from early morning till near midnight, he would gladly welcome to his house any professional brother who might be introduced to him, and of his great liberality and kindness to those of his patients who might not be prospering like himself, much can be said and told; the Harrogate physician was indeed one who carried out his religious profession in his daily work, and who thoroughly enjoyed doing acts of kindness and charity.

During his severe illness Dr. Kennion was most carefully attended by his friends in the neighbourhood, and on hearing of his danger his friend Sir Wm. Jenner at once went off to see him; for a time there were some hopes of a recovery, but these unfortunately were but transient, for it was decreed that the patient's work on earth was done, and the best human aid proved of no avail.

On Thursday, July 2, the mortal remains of Dr. Kennion were interred in the churchyard of High Harrogate. A large number of the carriages of the neighbouring gentry joined the procession, and among the medical gentlemen present were Dr. Myrtle, Dr. Bennett, Dr. Deville, Mr. Scaife, Mr. Short, Mr. Millner, and others from places at a distance from Harrogate.

DR. RAMSBOTHAM, F.R.C.P.

We have to announce the decease of this well-known physician, the last edition of whose standard work on obstetrics we reviewed a few months ago. Dr. F. H. Ramsbotham inherited, as all our readers know, a name illustrious in this branch of our art, and he bore it worthily through a long career, having reached the ripe age of sixty-seven. From the time he entered practice, he devoted himself to obstetrics, and was at an early age a recognised authority. He was a graduate of the University of Edinburgh. He began practice in the city, was Physician to the Royal Maternity Charity, and afterwards Obstetric Physician to the London Hospital, at the medical school of which he was for many years Professor of Midwifery. Later in life he left the city for the West-End. For some years past his health has declined, and a little more than a year ago he gave up his professorship. He had previously retired from practice. He died at Perth on the 7th inst., where he had been for a short time.

MATTEUCCI.

The Italian journals announce the death of this illustrious man. His fame is heard in all schools of science, and his name universally reverenced by the medical profession. He was minister of Public Instruction in Italy.

POUILLET.

This well-known author has also died at the ripe age of seventy-eight, to which he had retained the full use of his great faculties.

◆

Literature.

VACCINATION.

Those whose interest in vaccination has been sufficiently roused by recent pamphlets to desire to know all about the subject, as well as students generally, will do well to consult Dr. Seaton's Handbook,[1] which is at once the fullest and best manual on vaccination that has appeared. The position of the author as a medical inspector to the Privy Council has afforded him unusual opportunities of acquiring much information respecting details, many of which are exceedingly complicated, but all of which are clearly explained in the admirable volume before us.

MATERIA MEDICA.

Garrod's Manual of Materia Medica[2] has always been a favourite one, and we have much pleasure in stating that the third edition has been carefully revised so as to bring it down to the present day. The book is full of facts so well arranged, that there is no difficulty in finding everything by reference to its place in the work. At the same time, we should add that the index is very complete. We are very glad to find this manual has the edges cut by the binder, and we only wish publishers of other works of reference would follow the excellent example.

RODENT CANCER.

Mr. C. H. Moore has published some graphic illustrations of rodent ulcer of the face in a neat volume, which has been for some time in our hands.[3] The attention which Mr. Moore has paid to the subject of cancer generally, and the reputation he has established as a surgeon and author, will ensure candid consideration for whatever opinion he may advance. In the terrible disease commonly called rodent ulcer, and which causes so much disfigurement of its victim, Mr. Moore sees the characteristics of cancer, and names it accordingly. He thinks any constitutional property far from essential to cancer, and he seems to consider that cancer does not exist prior to its first manifestation as a tumour, and as an entity apart from that. We do not think it essential to endorse or controvert this idea. Our intention on the present occasion is only to mention the conclusions of a careful observer, who has met with great success in his treatment of these cases.

BANDAGING.

Mr. Fairlie Clarke has published as a small volume on Bandages and Splints,[4] a supplement to his Manual of Surgery. It is illustrated by seventy-eight good woodcuts, and forms a handy little pocket-volume. We have only one fault to find with it—that the necessary use of the paper-knife leaves the edges ragged and unsightly, and thus takes away some of the neatness every pocket-volume should possess. When will publishers attend to these little things, and compel binders to finish their work. Authors will soon have to see after such things themselves.

EDUCATION.

We have read with much interest a work on education,[1] just published by a Physician, who does not furnish his name, but has evidently bestowed much attention on the great subject he treats in four careful essays. He advocates a much further application of compulsion than we have as yet been convinced to be necessary, and he anticipates a complete social reformation by the enforcement of his proposals, which, although giving the children a much longer and more efficient training, would, he believes, cost less to the country. If everyone were to advocate his views with the same moderation as the author of these four essays, we should probably soon see much more agreement than has hitherto appeared likely to be ever attained.

PERIODICALS.

We have to notice the appearance, punctual to the day, of the two half-yearly volumes[2] that form so excellent an epitome of the practical papers that have appeared in the more frequently-published periodicals. We cannot indicate a preference for either—both are good, and both, we find, have watched our own pages, and those of our contemporaries. Everyone should possess one, and those who can afford it may advantageously take both.

Another number of the *Journal of Cutaneous Medicine* has been issued, with articles by Erasmus Wilson, Handfield Jones, Hoblyn, C. Drysdale, and others.

We should also mention another quarterly just received, the *Journal of Mental Science*, of which Dr. Maudsley is now coeditor.

The new therapeutical journal called the *Practitioner* has made its appearance as an elegantly got-up 8vo. We have previously announced it, and need therefore only say the first number is equal to promise. The exigencies of our space permit no more at present.

SENT TO COVENTRY.

It is not often that we have to comment on any practical and determined exhibition of unanimity in a large portion of our profession in any locality. Still less frequently do we have to express approval of a proceeding, at once so unusual and so severe, as placing a medical man outside the pale of professional recognition. Events have, however, lately occurred, which demand attention at our hands, and which we commend to our readers as of the utmost importance; for they indicate a determination to uphold the honour and dignity of our calling that has too often been found wanting; they show, too, an activity on matters of professional concern, and a readiness to sacrifice personal pecuniary interests for the good of the general body, that we are happy to make widely known.

It will be remembered that some months ago an attempt was made in South Staffordshire, East Worcestershire, and other parts, to place club practice on a better footing. Meetings were convened, evils discussed, remedies proposed, resolutions adopted. There was not, indeed, perfect unanimity on every point, but there was a general agreement as to principles. The medical men of Oldbury, for example, adopted 5s. as the minimum annual contribution of members of Friendly Societies to the medical attendant. Some other parts fixed the minimum at 4s.:—

The following important documents give full information, and are otherwise worthy of quotation:—

"RESOLUTIONS PASSED AT A GENERAL MEETING OF THE MEDICAL PRACTITIONERS OF SOUTH STAFFORDSHIRE AND EAST WORCESTERSHIRE, AT THE DARTMOUTH HOTEL, WEDNESBURY, ON THE 19TH OF FEBRUARY, 1868:—

"1. That we pledge ourselves not to accept any fresh appointment as surgeon to a club, at less payment than five shillings per head per annum, and we further bind ourselves from the date of this document not to become candidates for or allow ourselves to be elected to the office of surgeon to any society that may become vacant owing to the resignation or dismissal of the surgeon on the question of remuneration, at the above rate, or on any other question, under the space of six months after the rise has taken place.

"2. We pledge ourselves that between the present time and Christmas we will raise the annual payment of club members to five shillings, and we also agree not to attend any club whose rate of payment is less than five shillings per member per annum.

"3. That it is derogatory to the interest of the profession to admit children into sick societies except upon the same terms as Adults.

"4. That no person be admitted as a member (*to receive medical aid*) of any club who has not been examined by the medical attendant and considered eligible, both as regards health and social position.

"5. That no medical man return more than five per cent. commission on receipt of money, nor pay any premium on election in money or kind.

"6. That the foregoing resolutions be printed and circulated among the profession of the district, with a request that every medical man will attach his signature to each resolution, with any reservation he may think fit to make, and return it to the secretary. The resolutions, with their reservations, will then be submitted to a general meeting specially convened.

"JOHN MANLEY, Hon. Sec., West Bromwich."

"WE, THE UNDERSIGNED MEDICAL PRACTITIONERS OF WEDNESBURY, DARLASTON, AND HILL TOP, UNANIMOUSLY AGREE TO THE FOLLOWING RESOLUTIONS:—

"1.—That we will not accept any new appointment to a sick club originating from this date at a less sum than 5s. per head per annum.

"2.—That we undertake to issue notices to all sick societies to which we are now appointed, for a fee of 4s. per head per annum, from the entering on a new year, half-year, or quarter, as the case may be; each notice to terminate at Christmas at the outside.

"3.—That we further undertake not to accept any appointment, at any price, where the surgeon has been dismissed on the question of remuneration.

"4.—That we accept no appointment for six months after termination of notice on any other grounds.

"5.—That we undertake to return no commission, drink-money, nor stewards' fees, nor to become members, honorary or otherwise, to any society.

"6.—That we admit no member of any club to receive medical aid who has not been examined, &c.

"7.—That in future all salaries be paid at the surgeries of the respective medical attendants.

W. C. GARMAN,
CHARLES WEBB ILIFFE,
J. C. GARMAN,
RANSOME AND LATHAM,
G. E. HOWITT,
H. F. HANDY,
J. JOHNSON,
THOMAS SANSOME,
JOHN MANLEY, Hill Top,
THOMAS BLACKWOOD,
NORRIS WM. BEST,
WILSON MOORE,
SAMUEL PARTRIDGE."

A movement of this kind, accepted unanimously by the resident practitioners, and supported by the voice of the whole profession, might be supposed capable of overwhelming all opposition, and preventing any further attempt to grind down club doctors to a scale of pay unworthy of skilled workmen. Such, unhappily, has not been the case. Three persons have, it seems, been found ready to accept contracts repudiated by the whole profession, and have been introduced by the sick-club members to the districts for the express purpose of accepting these terms. We are not surprised that the practitioners of the districts have taken the extreme step with regard to these three persons, as will be seen from the following, to which we give due prominence:—

---

[1] Education and Training considered as a Subject for Legislation. By a Physician. London: J. Churchill and Sons.

[2] Half-yearly Abstract of the Medical Sciences. Vol. 47—Jan. to June, 1868. London: J. Churchill and Sons.

The Retrospect of Medicine. Edited by W. Braithwaite, M.D., and James Braithwaite, M.D. Vol. 57—Jan. to June, 1868. London: Simkin, Marshall, and Co.

> "At a meeting of the medical profession of South Staffordshire and East Worcestershire, held at the Dartmouth Hotel, Wednesbury, July 2nd, 1868, it was resolved:—
>
> "That taking into consideration the introduction of medical men into portions of these districts, who are acting contrary to the unanimous resolution of the profession, we pledge ourselves neither to meet them professionally nor socially; and we further pledge ourselves not to consent to meet in consultation any physician or surgeon who recognises them.
>
> "That a copy of the foregoing resolution be forwarded to the consulting physicians and surgeons of Birmingham and Wolverhampton, and to THE MEDICAL PRESS AND CIRCULAR, *Lancet*, and *Medical Times*."

We confess that our sympathies are entirely with the gentlemen who have passed the above resolutions. The persons affected are unknown to us, but we cannot imagine any justification for their conduct. Unless the voice of the profession is to be entitled to respect and obedience on a question like this, nothing can save it from the greatest degradation. We have no fear of honest competition, we have never been great sticklers for artificial rules of professional etiquette, but we see that unless in a question like this, the profession acts thus decisively, there is no hope whatever for the elevation of its poorer members. Whatever the sacrifice they have made, and no doubt it is considerable in a monetary sense, our northern friends have made it for the sake of their brothers in club-bondage throughout the kingdom, and when their action became nullified by the introduction of strangers into the district, who defied them and their professional brethren throughout the land, nothing was left for them to do but to take the extreme step they have done. This step, though it may not enforce their views, was the only one left, and will undoubtedly obtain for those who have taken it the approval of the united profession.

NOTES ON THE DEBATES OF THE MEDICAL COUNCIL.

THE sittings of our General Council having been concluded, we gather up here the fragments of its debates, in continuation of our former remarks.

Those interested by them will turn to the reports for detailed information.

PRELIMINARY EDUCATION.

The backward state of the education of the young gentlemen who enter the profession, has been strongly illustrated. Many are rejected at the preliminary examination for Latin, though the knowledge of that language exacted is only elementary. Then a very large proportion of students are rejected for ignorance of their mother tongue. Well might the Council hesitate to demand more. Less could not be accepted. We look forward to the time when no one will be suffered to enter the profession until he has given satisfactory proof of a liberal education.

FORENSIC MEDICINE.

The London College of Surgeons does not accept the recommendation of the Council to add this subject to the list of lectures to be attended. That College has always been ready to resist any suggested improvement, and as the Council has, after discussion, decided on certain subjects, we are not surprised to find the College object. Does that corporation wish to undersell all others still? Some improvements it has, indeed, carried out lately, but its concessions to public opinion were very tardy. It is a pity the Council has not laid down one scheme and compelled all the corporations to adopt it.

SECONDARY EDUCATION.

Why should the Council petition Parliament on this subject? The idea out of doors is that the Council would do better to confine its attention strictly to the education of medical men, and enforce such preliminary examinations as had its confidence.

A REAL POINT.

On Monday afternoon the Council spent a weary time in drawing up a resolution. The words having at length been decided upon, some further time was spent in discussing the proper position of a comma in one of the phrases.

Verily the Council can make a point of a small point. We, like most journalists, frequently leave punctuation to the printer. That may and does sometimes give rise to curious mistakes, and occasionally to annoyance, but then it is not so costly as the time of the 24 talented men who form the Council at five guineas a day each.

THE FRANCHISE OF THE CORPORATIONS.

This subject is attracting wider attention than ever out of doors. Dr. Paget's speech has produced great sensation, and it is thought that in another year he may have so far matured his views as to tempt him to take action. It will be remembered that he related how large was the constituency that had the *right* to vote in his own case (University of Cambridge). Dr. Bennett announced that the *Fellows* of the London College of Physicians could take part in his election, though he acknowledged that *practically* his election was the act of the Council. The Edinburgh Royal Colleges allow the *resident Fellows* a vote if they chose to exercise it. These facts are the thin end of the wedge, and upon them the weight of professional opinion must be exercised. A little firm expression and this great reform of the Council must be accomplished. Then although its representation may be said to be indirect, the profession will be very fully represented in the Council which it pays. Extension of the Franchise of the Corporations means, too, more than this.

PHARMACY.

The progress of pharmacy—the state of pharmacy—how much attention did not these phrases excite. Then the Pharmacy Bill too! That is a fine bone of contention. That the present condition of the practitioner of pharmacy is not satisfactory every one seems to see, but how to remedy it puzzles a good many. Should pharmacy be kept as a distinct calling, as is the case in most foreign countries? That, in our opinion, is the most important question to be settled about pharmacy.

◆

Notes on Current Topics.

Royal College of Surgeons of England.

THE annual elections came off on the 9th instant. Mr. Quain takes the president's chair, and Mr. Cock and Mr. Solly are vice-presidents for the year. Mr. Partridge, according to our prediction, is the new examiner in dental surgery.

The council has re-elected Mr. Huxley and Mr. Le Gros

Clark to their professorships, and appointed Mr. Hulke to the new lectureship on anatomy and physiology.

These appointments seem to have given general satisfaction.

University of Edinburgh.

THE Principalship has passed to Sir A. Grant. The curators have been deterred from giving it to Sir James Y. Simpson, by a protest of some of the other professors. Those who love Auld Reekie best will most regret to see the claims of Sir J. Y. Simpson thus set aside. What those claims are we have pointed out, and they have been endorsed by upwards of 800 graduates, who signed a counter memorial to that of the ten or twelve jealous professors who so unhandsomely interposed. The incident, however, demonstrates the absurdity of allowing so small a body as the curators to appoint the Principal. Surely the General Council will shortly demand a voice in the election. This is a reform for which the graduates are entitled to ask.

The only other thing that strikes us as worthy of mention—for the conduct of the professors we consider unworthy of our notice—is, that Mr. A. Black seems determined to disappoint the liberals who have trusted him out of Parliament as completely as he did those who had faith in his Liberalism when he went into the House.

The Abyssinian Medical Service.

THE Abyssinian Army has received a vote of thanks from Parliament. No mention was made of the Medical Service. Many are indignant. Our contemporaries write long effusions. But this will always be the case until the profession makes its power felt in politics. How very few heartily support our too few medical politicians! If practical men ignore politics let them not grumble that the profession is ignored. A few doctors in the House of Commons would change all that.

Chloroform.

AMONGST the deaths recorded from the use, or rather misuse, of this anæsthetic is that of the wife of an American officer, who, according to *The Pacific Journal*, placed a handkerchief containing a few drops of chloroform to her mouth, in the hopes thereby of getting relief by sleep from the pain she was then suffering. Unfortunately for the poor victim, it took effect in the way she so much desired. It soothed her to sleep; but it was to a sleep from which she never awoke. The morning found her a corpse. Cases of a similar kind, where chloroform is sold indiscriminately by chemists to the general public, without any inquiry being made, or caution as to its effects being given, constantly come under our notice. And we hope that some prohibition will be extended to this—in unpractised hands—dangerous article, in the "Pharmacy Bill" now before the legislature.

Glazing the Streets.

LONDON people complain bitterly of the slippery nature of the streets. When the water-carts have done their duty the pasty, agglutinous mud renders it next to impossible for horses to keep their legs. The city authorities are pre-eminently neglectful. In driving through the city last week we witnessed the fall of several fine horses, and our coachmen told us that his friends heartily wished the Lord Mayor might be pitched out of his carriage. He said he once saw one of his Lordship's predecessors thrown out from the slippery state of the streets, after which he noticed that they were regularly gravelled.

We wish evil to none, and a little gravel might surely be granted without risking the life of a Lord Mayor.

Evils of Bad Cooking.

A CORRESPONDENT of the *Nashville Journal of Medicine and Surgery*, writing from Paris, thus expresses himself: "I have spoken of the denizens of this gay, voluptuous capital as being less cleanly than becomes good taste or sound principles of hygiene, but I will do them the justice to say they are masters in the culinary art; and I will add that since I came to their capital I have known one inveterate case of dyspepsia cured by French cooking, and the disuse of tobacco. Such is my appreciation of this art, as one of the great means of promoting health, that I would, have all our girls taught that, next to being amiable and unselfish, the great aim of a woman's life should be to become a good cook. I verily believe that bad cooking is the cause of much of the wickedness that is in the world, and the source of more than half of the domestic infelicity. Bad cooking, I am convinced, killed more Confederate soldiers than were killed by the Yankees. I am not sure that habitual bad cooking ought not, by law, to be made a sufficient cause for divorce, as, I believe, habitual drunkenness is in some of the States. If young women would study cooking as much as they study music, and spend half as much time in their kitchens as they give to their pianos, there would be more harmony in their houses if less music. The millennium cannot come, of course, until sin ceases in the world, but sin can never disappear while the brains and nerves of men are tortured by unwholesome blood, the result of bad cooking; and so I conclude that the man who improves the cookery of his country is one of its true benefactors—certainly the peer of him who makes 'two blades of grass to grow where one grew before.'"

Muzzling Dogs.

THE protest raised on behalf of our canine friends is a just one. As a dog perspires through the mucous membrane of his mouth, by forcibly keeping it closed we prevent him cooling himself. The large wire muzzles that leave the dog the opportunity of drinking, are less cruel than the simple strap closing the mouth, and should be preferred by all humane masters while the police edict is in force.

Dust-bins.

WE have again and again called attention to the family dust-bin as a focus of disease. In fact, for years past we have at intervals urged our readers to draw the attention of their patients to this subject. The obstinacy and blindness of servants, to say nothing of their idleness, disposes them to make the dust-bin the general receptacle of filth. Hence it becomes not only a nuisance but a source of great danger.

We are glad to find that some Medical Officers of Health have become more alive to the subject, and that our contemporaries are ready to enforce the necessity of doing so. Foremost of all, as it ever has been on this and allied topics, is the *Builder*, which continues its valuable services in sanitary matters.

AT the monthly meeting of the Royal Society of Great Britain, Sir H. Holland, Bart., in the chair, the managers announced that, in conformity with the deed of endowment, they had appointed William Odling, Esq., M.B., F.R.S., Fullerian Professor of Chemistry, in the room of the late Professor Faraday.

Last week, a petition from a number of ladies, members of a body termed the Female Medical Society, presented a petition to the Council of the Farringdon Dispensary and Lying-in Charity, praying that they might be admitted to the practice of the dispensary. After a somewhat noisy discussion, a resolution proposed by Dr. Palfrey and seconded by Mr. Figgins—"that the petition be not acceded to"—was carried by a large majority. We believe we are correct in stating that this is the second time during the past year that the committee have refused their sanction to the introduction of females to the practice of the charity.

Mr. Bailey, M.R.C.S., is a candidate for the representation of Athlone in the next Parliament. Mr. Baxter Langley, M.R.C.S., has issued an address to the electors of Greenwich. There are rumours of some other medical candidates, but they are as yet only rumours. We certainly need more medical M.P.'s, and sincerely hope that the profession will support its own candidates.

Amongst the medical men whose names have been mentioned as candidates for Parliamentary honours under the the new Reform Act, is that of Dr. Forbes Winslow, the well-known author of "The Incubation of Insanity," and various writings connected with Diseases of the Brain. This gentleman had been solicited, and had allowed himself to be nominated for the joint Universities of Glasgow and Aberdeen, from the latter of which he obtained the degree of M.D. in 1849. As soon as he became acquainted with the fact that the Lord Advocate intended to contest the constituency, and had already received many promises of support, Dr. Winslow withdrew from the candidature, being unwilling to divide the Conservative chance of success.

We have been requested to inform our readers that the Council of the Metropolitan Poor-law Medical Officers' Association have resolved to recommend at the annual meeting a change of name, and to extend the Association to the Provinces. It is proposed to drop the word Metropolitan. We have always urged this plan.

A patient having lately committed suicide by throwing himself from a hospital window is a warning that such institutions might very well have bars so constructed as to render such tragedies impossible.

The portrait of Sir Thomas Watson is engraved. The *Fellows* of the College of Physicians propose, with that condescension which they occasionally exercise when money is concerned, to permit such of the *members* as may feel inclined to assist them to pay for it, by purchasing such copies as may remain after the Fellows have selected theirs. No doubt some members will rush to obtain the leavings of the Fellows.

Dr. Charles Hood has been knighted by the Queen.

New Fellow.—At a meeting of the Council of the Royal College of Surgeons on the 9th inst., Mr. Thomas Watkin Williams, Newhall-street, Birmingham, diploma of Membership, dated April 3, 1840, was admitted a Fellow of the College.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

Friday, July 4.

(Continued from page 45.)

After the report containing the recommendations of the committee on Preliminary Education had been read—

Dr. Alexander Wood, as chairman of the committee, moved—"That it be recommended to the licensing boards not to accept the certificate of proficiency in general (preliminary) education from any of the bodies, the names of which are contained in the list annually circulated, unless such certificate testify that the student to whom it has been granted has been examined in—1. English language, including grammar and composition. 2. Arithmetic, including vulgar and decimal fractions. Algebra, including simple equations. 3. Geometry: First two books of Euclid. 4. Latin, including translation and grammar."

Dr. Apjohn considered it perfectly useless to attempt an enforcement of the subjects proposed by the Committee; the matter had, he thought, been long since settled, and he felt persuaded that the University he represented would not consent to be hampered by such minutiæ.

Dr. Parkes thought the list could scarcely be objected to on the score of severity. It had been considered by some members of the Council to be not severe enough; but he thought anybody reading it carefully would see there was nothing in it that might not reasonably be required from young men of 17, and there ought to be no hesitation on the part of the Counsel in recommending the licensing bodies to require that extent of education at least.

Dr. Paget did not understand Dr. Apjohn to object to the list as being too severe, but rather that there might be examinations far above the mininum prescribed by the Council, but which nevertheless might not include clearly and distinctly all the subjects—such, for instance, as English Grammar. If it were possible so to word the resolution as not to encounter that difficulty, it would be an advantage, because otherwise the Council might come into collision with bodies that were really doing more than the resolution asked, simply because they did not conform literally to all its recommendations.

Dr. Alexander Wood said this was the original standard which had been laid down by the Council, and approved year after year. The Committee, having sat upon the question, found in point of fact that obedience was not accorded to the recommendations of the Council, and they now suggested how those recommendations should be enforced. The only thing to be done was, if the examinations did not conform to the requirements of the Council, they must not be recognised. The Council must insist upon conformity with the list drawn up by the Committee as the minimum, because if they agreed to what Dr. Paget suggested—to allow laxity in one subject because the examination was high in another—who was to be the judge? It would be, in point of fact, better for the Council to give up its educational supervision altogether than to admit such a principle.

Dr. Andrew Wood said the Council had issued certain recommendations to all the licensing bodies of the kingdom—to the Colleges of Physicians and Surgeons, and various others; and they had been, most satisfactorily, doing all in their power to comply with those recommendations, until they had raised their standard up to that recommended by the Council. He was not, then, prepared to admit that bodies, over whom they had no power of visitation, should be allowed to say—Because we examine upon so and so, therefore we consider that an equivalent for something else.

Dr. Paget: That is not what I suggested.

Dr. Andrew Wood: It is equivalent to what you suggested. It would never do to open the meshes of the net in that way, because if they did it to one they would be required to do it to all, and would be retrograding instead of advancing in Medical Education. If those bodies whom they had hitherto recognised did not choose to come up to the standard laid down by the Council, they must disfranchise themselves. He therefore trusted that Dr. Alexander Wood would persevere, and that there should be no vacillation and uncertainty with regard to the matter.

Mr. Cooper could speak of the Apothecaries' Hall as a body who carried out most strictly the recommendations of the Council; and the consequence was that in the examination of January last forty-one gentlemen applied to be examined, but only thirty-five were admitted, of whom eighteen passed, and seventeen were rejected; and of the latter, eight had been previously rejected. With such facts before them, he thought they should not increase the severity of the preliminary examinations. Above all, however, every student should have a positive knowledge of his mother tongue, a knowledge of Latin, and he could wish a knowledge of Greek, in order to enable him to understand the technical terms of science; but he very much doubted whether the secondary education in the kingdom was such as would warrant the Council in requiring too severe a curriculum.

Mr. **Cæsar Hawkins** questioned whether it was wise to lay down minute rules for such bodies as Oxford, Cambridge, and Dublin, whose standard must be higher than the minimum required by the Council.

Mr. **Hargrave** differed from Dr. Apjohn that the University of Dublin would not agree to the terms of the Council—he believed they would comply at once.

Dr. **Storrar** called attention to resolutions already passed by the Council in reference to this matter, and added that Dr. Parkes had not used too strong an expression when he said that those were solemn decisions of the Council come to upwards of two years ago. Fair notice had been given to all educational bodies of this determination of the Council, and now, because those bodies had not chosen to put themselves in a proper position with regard to the Council, it was attempted to be said that the recommendations of the Council should be altered for their convenience. If they yielded one inch upon this question, they might as well throw up their duties altogether.

Dr. **Paget** moved what would properly come as a rider to the resolution, for the purpose of taking the opportunity of explaining what he meant (which seemed to have been entirely misunderstood) by the objection he took to the resolution. It was not an examination in English that he objected to at all; but it was that bodies like the ancient universities of England should be obliged to conform to all the minutiæ pointed out in the resolution. He would therefore move to rescind the resolution of the Council of June 6, 1867—

"That the General Medical Council will not consider any examination in English sufficient that does not fully test the ability of the candidate—1st. To write a few sentences in correct English on a given theme, attention being paid to spelling and punctuation, as well as to composition. 2nd. To write a portion of an English author to dictation. 3rd. To explain the grammatical construction of one or two sentences. 4th. To point out the grammatical errors in a sentence ungrammatically composed, and to explain the nature. 5th. To give the derivation and definition of a few English words in common use."

And, in conclusion, he would ask Dr. Storrar whether, in the University of London, students were required to write a portion of an English author from dictation.

Dr. **Storrar**: Yes.

Dr. **Paget**: Well, I must confess I doubt whether my university would think it a necessary thing.

The debate was then adjourned.

Saturday, July 4.

The adjourned debate on the report on Preliminary Examination was continued by

Dr. **Paget**, who said that in cases where there was an examination more extensive and more difficult than the minimum proposed by the Council, such examination should stand as a substitute for the minimum required by the Council—in other words, that the major should include the minor. The curious effect of the resolution of Dr. Alex. Wood, coupled with the previous resolution of the Council last year as to the mode of conducting examinations, would be this—that graduates of Cambridge, and he believed of the other ancient universities, would not be able to receive certificates of having passed the examination now required by the Council. Because such a test as writing from an English author from dictation was not applied at Cambridge, therefore a man might have taken the highest honours in classics, mathematics, and natural science, he might be, and ordinarily would be, 23 years of age, he might be as well able to write good English as any member sitting on the Council; yet, after all, that he would not be allowed to begin his medical studies. True, he might have passed his examination in writing from dictation from an English author when he was a boy of 12 or 14; but, inasmuch as the university did not apply that test, it could not give the certificate that would be required.

Dr. **Alexander Wood** said that laws were not made for the good, but for the bad, and that it was known as a positive fact there were men seeking to enter the Medical Profession every day who, whatever might be their knowledge of Latin, Greek, or mathematics, were utterly ignorant of their mother tongue. In order to remove all difficulty, he was content to modify the resolution by inserting the words, "Provided also that the Branch Council may accept any examination which seems to them equally to secure on the part of those passing it a sufficient grammatical knowledge of English."

The debate was continued by Dr. Andrew Wood, Dr. Thomson, Mr. C. Hawkins, Sir Dominic Corrigan, Mr. Hargrave, Dr. Apjohn, and others, and the resolution was finally adopted in the following form:—"That, in reissuing the regulation regarding the examination in English adopted last year, the following be added—'Provided always that an examination may be accepted as satisfactory that secures on the part of the candidate passing it, a sufficient grammatical knowledge of English.'"

THE SUPERVISION OF PRELIMINARY EXAMINATIONS.

Dr. **Alexander Wood**, in introducing the second paragraph of the report, said the Committee had to consider "whether any plan could be devised by which the Council could better supervise the preliminary examinations." He would move, "That the Branch Councils be requested to make arrangements for visiting and reporting on such preliminary examinations as have not already been visited, and regarding which it may appear to them desirable to procure information. That the reports made on these examinations be transmitted in the usual manner to the Executive Committee for the consideration of the General Council at their next session."

After a few remarks from Sir Dominic Corrigan, Dr. Apjohn, Dr. Storrar, and Mr. Hargrave, the paragraph was agreed to.

GENERAL EDUCATION.

Dr. **Alexander Wood** said the Committee, having taken this matter into consideration, he begged to move the following resolution:—"That the Executive Committee be instructed to watch over any Bill on general education with a view to such arrangements as will enable the various boards to secure the due preliminary education of Medical students."

Dr. **Storrar** seconded the motion, and it was carried *nem con.*

CENTRALISATION OF EXAMINING BOARDS ON PRELIMINARY EDUCATION.

Dr. **Fleming**, in introducing this subject, moved—"That it be remitted to the Branch Councils to consider and report how far it would conduce to a more efficient and satisfactory system of conducting the examination of students in preliminary education if a board was appointed by each Branch Council to arrange and conduct, under their supervision, these examinations; and that should the Branch Councils approve of such a system, they be requested to indicate the method by which they would propose to carry it out." At one period he had been of opinion that it would be better to withdraw these examinations from licensing boards altogether and place them entirely in the hands of the National Education Boards; but from what he had seen and heard it was his belief that confidence could not be placed in them, and that if the Council could organise some central plan, it would be both a great facility for students and also an advantage to the profession at large. Taking London, for instance, he would suggest that the Executive Council should appoint a committee of five examiners, who should prepare a list of questions which, upon being printed, should be sent down to the various licensing bodies. The students would then write their answers to those questions, and they would be returned to the examiners, who would judge upon them and decide whether the candidates deserved to pass or to be rejected. In regard to the expense, it could be met if a fee of ten shillings were exacted from every student coming up for his preliminary examination. One of the principal recommendations of this scheme was that it would prevent—what was too common at the present time—students saying, "I will go to this board or to that, and see if they will pass me, and if I am rejected I will go to the Apothecaries or some other body and try them." He knew that that was done in Scotland, and he had no doubt the same thing occurred in the other divisions of the kingdom.

Sir **Dominic Corrigan** thought this was a step in the right direction, because it would ensure that young men entering the profession had a sufficient preliminary education, which was not secured under the present system, and he believed never would be, while they had something like twenty-two or twenty-three bodies entitled to issue certificates for preliminary education, over which bodies the Council had but little control. It was their fatal lukewarmness with regard to general education that produced such scenes as that described by one of the daily papers, which he, as having taken place in the House of Commons, would read for their instruction:—"Non-combatants in Mounted Corps.—Captain Vivian asked why non-combatant officers were appointed to mounted corps and compelled to pay ration, although they received no mounted pay? Sir J. Pakington said it was impossible to deny that, especially as regards medical officers, there was an inconsistency in the system, but, notwithstanding this, medical officers are always found anxious to obtain employment in cavalry regiments." He would like to know would Sir John Pakington say the same thing of his own office—namely, that if the salary was only £100 a-year it should not be increased because there were to be found many persons ready to take it at that rate! The reason medical men were treated in that way was quite in accordance with the well-known axiom of political economy—namely, that in proportion to the abundance of the supply the price of the article would be depreciated. By narrowing the door of preliminary education they would remedy this evil, and, at the same time, raise the status of the whole profession. If, next year, all the licensing bodies rejected 70 per cent., instead of 25 per cent., neither society in general nor the medical profession in particular would sustain a very great loss from the absence of the other fifty who were declared unfit to enter the profession. He was, moreover, of opinion that society would go on very well, and perhaps a good deal better, without any doctors at all than with bad ones.

Dr. **A. Smith** expressed his entire concordance with the motion of Dr. Fleming.

Dr. **Storrar** said, anxious as he was to see it realised, there was no power to do what was suggested without an Act of Parliament. They could only recommend it to the various bodies. He would offer a word of encouragement to those bodies which had courage enough to honestly raise their standard: that it had the effect of increasing the number of candidates. For whatever might be said about their being a body of students who were anxious to get through their examination on the easiest terms, there was a very large proportion who would never be satisfied unless they got the "best thing going." He mentioned as an illustration that three years ago there had been a very merciless rejection at the matriculation examination of the University of London; but notwithstanding that, the number of students in the succeeding years had very largely increased; and this year in particular they had a very large addition to boast of; he therefore contended that those schools who insisted upon a high standard would receive the greatest number of those men who would not fail to pass with credit to themselves, and honour to the body accredited with their education.

Dr. **Paget** would move that the resolution be amended as follows:—"That it be remitted to the Branch Councils to consider and report how far it would conduce to a more efficient and satisfactory system of conducting the examination of students in preliminary education, if boards were appointed by the General Medical Council, or by the Branch Councils respectively, to arrange and conduct, under their supervision, these examinations; that should the Branch Councils approve of such a system, they be requested to state the method by which they would propose to carry it out, or any difficulties which may stand in the way of doing so; and that these reports be transmitted to the Executive Committee at least one month before the next session of the Council."

The **President**, while agreeing with much that had been said, thought it should be publicly known, for the defence of the Council, that although they were one and all most anxious to raise the education of the profession, both preliminary and professional, they must always bear in mind that their regulations were not intended for men who were aiming at the highest honours of their profession. He thought the hon. and learned baronet and others had rather gone beyond what was just, in making a comparison between the requirements of the Council and those of such a body as the University of London. Those who came under the latter went of their own free will, and for the purpose of obtaining a very distinguished degree, but it was totally different with the students for whom they were called upon to legislate.

Dr. **Fleming** having expressed himself in favour of the amended motion, the same was then adopted.

THE STUDY OF GREEK.

Dr. **Alexander Wood** proposed:—

"That the Medical Council, while unwilling to come to any resolution that will have the appearance of lowering the standard of preliminary education, is of opinion that the year 1870 will be too soon to transfer Greek from the optional to the compulsory subjects."

Dr. **Embleton** seconded the motion.

Sir D. J. **Corrigan** totally dissented from the resolution, and it was the paragraph in the report which made him say the tone of the document was retrogressive. In Ireland the term grammar schools simply meant charity schools, the education of which was totally insufficient for any one intending to enter the medical profession.

Mr. **Hargrave** thought it would have the effect of postponing the study of Greek not only to the year 1870, but to the Greek Kalends.

Dr. **A. Smith** was quite convinced that if the Council required Greek from the candidates they would obtain it. He was quite prepared to undertake the responsibility on behalf of the college he represented, and he hoped the Council would insist upon the subject being required.

Dr. **Storrar** thought that for the sake of thoroughness it was well to postpone the subject of Greek for the time stated, because he thought sufficient notice had scarcely been given. For that reason, and for that reason only, he would support the resolution.

Dr. **Acland** supported the motion on the ground stated by Dr. Storrar. He would admit that Greek was very essential in the higher branches of professional knowledge, but there was a general inclination gaining ground in the country to substitute foreign languages as an alternative for Greek; it would therefore be better to defer it.

After a few remarks the motion was put to the meeting and carried by a large majority.

THE STUDY OF LOGIC.

A resolution upon this subject:—"That the Branch Councils be instructed to consider and report how far it be desirable to add some knowledge of the elements of logic to the preliminary examination of the medical student, and, if considered desirable, how it could best be carried out," moved by Dr. **Alexander Wood** and seconded by Dr. **Rumsey**, was passed unanimously.

A resolution endorsing paragraph eight of the report was also carried *nem. con.*

The Council then adjourned.

[The report of the Pharmacy Committee and the interesting debate thereon are unavoidably postponed till our next issue.]

REPORTS OF THE VISITORS OF EXAMINATIONS.

(1867-68.)

1. ENGLISH UNIVERSITIES AND LICENSING BODIES.

University of Durham.

The Committee have already noticed the addition of Euclid and Algebra to the subjects of examination for the Registration of medical students. The Reporters state that "in all the papers the questions are good, though rather easy. If a high standard of answering be enforced, such an examination may serve well for the present as a minimum test of general education."

With respect to visitation of other examinations in England, *see* resolution of English Branch Council, Minutes of General Medical Council, June 27, 1868.

2. SCOTTISH UNIVERSITIES AND LICENSING BODIES.

University of Edinburgh.

Preliminary Examination.—The Suggestions made by the Reporters last year for the improvement of the examination in English have this year been fully carried out.

University of Aberdeen.

Examination on Clinical Medicine and Surgery for the Medical Degree.—The Report states that the Examination is quite satisfactory.

University of Glasgow.

Preliminary Examination in General Education.—It appears from the Report that this Examination is not, in all respects, satisfactory. "The extensive alterations in it proposed by the University show that they themselves are not satisfied with it," and there can be no doubt "that under the new regime it will be greatly improved."

Examination in Botany and Chemistry for the Medical Degree.—A very satisfactory Examination.

Clinical Examinations in Medicine for the Degree in Medicine.—The Examination is thorough and complete. A detailed account of it is given by the Reporters.

University of St. Andrews.

Examination for Degree of M.D.—All the candidates were registered Medical Practitioners above the age of forty years. The Examination was both written and oral, and the plan pursued was "judicious and well-arranged;" but there is no mention of any Practical or Clinical Examination.

Royal College of Physicians of Edinburgh.

Examination of candidates who already possess a qualification.—This is exclusively oral. The Reporter states that it "is in every respect highly creditable to the College." There is no mention of any clinical Examination.

Royal College of Surgeons of Edinburgh.

Examination in Clinical Surgery.—"A thorough and fair test of the practical knowledge possessed by the candidates."

Faculty of Physicians and Surgeons of Glasgow.

Preliminary Examinations.—"On the whole, this is a satisfactory examination, and creditable to the Body by which it has been instituted."

Clinical Examinations in Medicine and Surgery.—These Clinical Examinations have been introduced since last year. The Reporters state that they are conducted satisfactorily.

Double Qualification of the Royal Colleges of Physicians and Surgeons of Edinburgh.

Preliminary Examination.—Some of the candidates had passed on several subjects previously. Of the five subjects of Examination, three only were compulsory, viz., English, Latin, and Arithmetic: the other two were allowed to be selected at the option of the candidate. This option would enable a student to avoid Examination in Geometry and Algebra.

First Professional Examination.—Reported to be "fair and judicious;" but in Chemistry, no analysis or testing was required.

Final Examination.—Reported to be "sufficiently extensive, varied, and searching, and yet not unduly difficult."

Double Qualification of the Royal College of Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.

"No practical or analytical test was applied to the candidate during his Chemical Examination."

3. THE IRISH UNIVERSITIES AND LICENSING BODIES.

University of Dublin.

The accuracy of this report having been questioned by the representative of the University, the Committee have conferred with the Reporter, and have ascertained that on one point there has been misapprehension. The report disapproves of the supposed practice of the University of announcing publicly the failure of a candidate. The Committee have ascertained that such is not the custom.

Moreover, the statement that the Examiners are the Professors seems to require some qualification, or at least explanation. Two of the Examiners are not Professors, and two of the Examiners, though Professors, are not Teachers.

The Report of last year referred to the Surgical Clinical Examinations as excellent. At the visitation now reported there seems to have been no clinical Examination either in Surgery or Medicine.

After a few remarks on the foregoing report by Dr. WOOD and others,

Dr. APJOHN stated, that the publication of the report of the committee on the visitation of examinations, has been attended with much inconvenience, and been productive of considerable injustice. It professes to present a complete view of the nature and extent of the examinations of the different licensing bodies, and then comments upon their supposed relative degrees of merit or demerit. Unfortunately, however, some of the condemnatory statements are not founded on facts, and hence an undeserved obloquy has been cast on certain of the licensing bodies. The part, for example, of the report which relates to the University of Dublin, is specially obnoxious to this criticism, for it alleges that "the mode of carrying on the oral examination (examining in class) is peculiar to this University." This is quite incorrect, for the very same method of examination is adopted at the King and Queen's College of Physicians in Ireland. In the report of the committee to which I am referring, the opinion is also expressed that such method of examination "cannot be so efficient as the ordinary plan of examining each candidate apart." I do not know the grounds of opinion here expressed by the chairman of the committee, but, I presume, it has been founded on a report by Dr. Leet of a visitation of an examination, held last October in the University of Dublin. Dr. Leet was the visitor, and the following is the passage to which I allude:—

"The questions (Dr. Leet reports) were judiciously selected, and appeared to be well qualified to test the candidates' knowledge; but in consequence of the *viva voce* questions being passed round the class, the answers did not tell to advantage, and I was not able to form a correct judgment of their value." Now, all this is quite possible, and, indeed, much of it is, I am sure, quite correct, but I do not see that *examination in class* is in the slightest degree damaged or even impugned by these remarks, for though the answers did not tell upon Dr. Leet, and that he was unable to judge of their value, he does not allege, and, I am sure, did not mean to convey, that the candidates or the examiners were in the same predicament as himself. Indeed, I am not without hope that on reflection, Dr. Leet will concur with me in thinking it would be very unreasonable in a visitor to pronounce an examination insufficient, merely because he found himself unable to follow the questions of which it consisted. I now, sir, turn to the *suggestions* in the report of Dr. Leet, the first of which is couched in the following words:—

"That no medical or surgical qualification be conferred upon any person who has not graduated in arts, and that the university should discontinue to grant licenses in medicine and surgery."

Now, Mr. President, this is a proposition which appears to me —not to use a harsher term—irrelevant in the highest degree. Such is the view which has been taken of it by the chairman of the committee, Dr. Andrew Wood, who judged it to have no relation whatever with the duty imposed on the visitors of examinations. It is not very easy to conceive what Dr. Leet's object could be, except that of giving gratuitous offence, for his recommendation is altogether impracticable—in fact, incapable of being carried out except through the intervention of an Act of Parliament. I may observe, too, that it comes with very little weight indeed from the representative of a trading company, whose acquaintance with university practice and privilege is necessarily very limited, and whose counsel, therefore, on the important questions of which he has so flippantly disposed, is altogether valueless.

Shortly after, at a particular stage in the reading of his report by Dr. Paget,

Dr. APJOHN drew attention to several erroneous statements by Dr. Hargrave in relation to the medical and surgical examinations held in the University of Dublin. It was not true that, as alleged by Dr. Hargrave, at the close of the examinations the names of the unsuccessful candidates, as well as the names of those whose answering had been satisfactory, were read out by the Regius Professor. It was not true that the teachers in the school of physic were the only examiners; and it was equally untrue to say that the candidates were not tested in the writing or dictating of prescriptions. These mis-statements were, he (Dr. Apjohn) knew, noticed in the report now under consideration; but, as the representative on the Medical Council of the University of Dublin, he was anxious to give them a direct and public contradiction.

Queen's University in Ireland.

Examination in Anatomy, Physiology, Chemistry, Botany, and Materia Medica.—The Reporter states that the oral Examination "was conducted *practically* in the case of all the subjects specified, with the exceptions of Chemistry and Pharmacy; and a longer time was given to the examination of each candidate than on the occasion of my former visit; each being subjected to a sufficient test of proficiency in the several subjects of examination, with the two exceptions referred to.

"Three Professors conjointly carried on the Anatomical Examination, and one Professor, singly, conducted each of the others."

King and Queen's College of Physicians in Ireland.

"Should a candidate fail at an examination he can be re-examined, but not until two months have at least elapsed since the time of his rejection."

"All the Fellows and Licentiates of the College may be present at the examinations."

"The College will, as heretofore, permit the student to qualify in Arts at any time within the first two years of professional study."

The Committee draw the attention of the Council to this fact.

At this visitation "seven gentlemen presented themselves as candidates, all of whom were Licentiates of the Royal College of Surgeons, Ireland, and were therefore, by a Bye-law of the College, relieved from examination in Anatomy, Physiology, Practical Anatomy, Chemistry, and Practical Chemistry, and interrogated solely in the senior or more practical portion of the Medical curriculum. The candidates were seated on one side of a table, and opposite to them were the four Examiners, two on each side of the President. Of these, two examined in the Practice of Medicine, one in Midwifery, and the fourth in Materia Medica; but there was no Examiner in Medical Jurisprudence, though the latter is one of the subjects which is placed by the regulations of the College in the second or practical part of the examination for the Licence. The examination commenced at ten minutes past 4 o'clock, the questions being proposed in turn to the several candidates, and when missed by one, passed to the next, and so on in succession; and it concluded at forty minutes past five o'clock, so that its duration was one hour and a half. The number of questions given by each Examiner was about eight, and the time occupied by each Examiner about thirty minutes."

The paper on Materia Medica contains some questions on Toxicology, but none on other parts of Medical Jurisprudence.

The time (one hour) allowed to candidates for writing their answers seems far too short.

In case of a difference of opinion among the Examiners, "the admission or rejection of the candidate would not be left to the Examiners, but would be determined by a majority of the votes of all the Fellows present, who might choose to exercise a voice in the matter," who (as the Committee understand) may, or may not, have been present at the entire Examinations, and may never have seen the written answers.

At a second visitation of these Examinations, the Reporter "was informed that there were no written questions, and that such were only proposed at the Quarterly Examinations."

There is no mention of any Clinical Examination.

The following suggestions are made by the Reporter:—"In the first place, I would recommend that the Bye-law which places Medical Jurisprudence among the subjects which constitute the second or senior part of the Examination for the Licence be strictly complied with, and fully carried out. It is an important practical branch of medical education, and there can be no difficulty in providing a suitable Examiner, seeing that the Professor in this department attached to the School of Physic is appointed by the College. If this course be not taken, it will at least be necessary to remove Medical Jurisprudence from among the subjects on which, as is announced at present, Candidates for the Licence will be examined.

"In the second place, it appears to me that the practice of varying the Examinations so as sometimes to have paper along with *viva voce* questions, and sometimes only *viva voce* questions, is very objectionable, and ought to be abandoned. No examination can be considered sufficient, in which the knowledge of the candidate is not tested by paper questions.

"Lastly, the College should insist upon the Examiners complying strictly with its printed rules in relation to the manner of conducting the Examinations, and the adoption of a numerical method of recording the answering of the candidates."

The Committee entirely agree with these remarks.

Royal College of Surgeons in Ireland.

Preliminary Examination.—"The constitution of the Board of Examiners is a very sufficient guarantee of their fitness for their duty."

The subjects of Examination were Arithmetic, English, Latin and Greek.

The results of the Examination were judged thus:—"A nought in any one of the subjects of examination insured the rejection of the Candidate." "About thirty-three per cent. was considered sufficient for 'pass.'"

"The Examination in the Greek and Latin languages was well conducted to test the acquirements of the Candidates, but many of them possessed a very imperfect knowledge of Latin Grammar; and in several instances it appeared that, although the Candidates could read and translate Greek, they did not know the correct pronunciation, or the Greek names of the letters."

The Reporter states that he cannot give any opinion respecting the proficiency in Arithmetic and English, as he did not see the answers sent in by the Candidates.

The number of Candidates was 42. The Reporter was informed that 8 were rejected. "One of the Candidates admitted that he was only fourteen years old, and two that they were only fifteen; four or five others appeared to be about the same age."

The Reporter observes that—"The fact of admitting boys of the ages of fourteen and fifteen years to pass a preliminary examination preparatory to becoming Registered Medical Students is one which deserves the attention of the General Medical Council, more particularly because the Council has recommended that no Medical or Surgical qualification should be conferred on any candidate who had not attained the age of twenty-one years."

The Committee are of the same opinion.

Examinations for Licence to Practise Surgery.—These examinations are generally defective; the defects which were noticed last year remain uncorrected. There is neither Practical nor Clinical Examination.

Apothecaries' Hall of Ireland.

The Report includes an Examination in Arts, and the first and final Professional Examinations.

Rejection in the first (Professional) Examination hardly ever takes place.

"The Examinations in Chemistry, Inorganic and Organic, in Botany, General and Medical, Materia Medica, and General and Practical Pharmacy, embraced a great number of questions, which were admirably put, and must be considered as a searching test of the knowledge of the candidates in these departments.

"Those in Anatomy and Physiology, on the other hand, were of the most elementary description."

The Reporter states, "As to the Professional Examination, which includes the Principles and Practice of Medicine, Surgery, Pathology, and Therapeutics, Midwifery, Forensic Medicine, Hygiene, and Toxicology, I cannot give any report, except from one instance. On the occasion of my first attendance the Examination was confined to its first part, and on that of my second, there was but one of the candidates who had to undergo the second or Professional Examination. This candidate was a Surgeon. He was well examined in Therapeutics; but in Medicine and Pathology the Examination was extremely limited, and could hardly be taken as a test of sufficient medical knowledge."

In making the foregoing extracts from the Reports of Visitations of Examinations, the Committee have had in mind rather to point out defects than to record acknowledged merits. They have had solely in view the means of further improvement and perfecting of the Examinations; but they desire to add their conviction that there has already been a general and very great improvement in the Medical Examinations throughout the United Kingdom during the short period since the Medical Council directed its attention more particularly to this subject.

The Committee are confident that this general progress of improvement in the Examinations must lead, and is already leading, to improvement in the acquirements of Medical Practitioners.

In conclusion, the Committee would suggest the adoption of the following Resolution:—

That the General Medical Council are of opinion—

I.—That it is desirable that the different Licensing Bodies should combine their Examinations, when this is practicable, so as to secure that the knowledge of every practitioner, whose name appears on the Register, shall have been tested in all the subjects of Professional Education which the Council has determined to be essential, viz.:—1. Anatomy. 2. General Anatomy. 3. Physiology. 4. Chemistry. 5. Materia Medica. 6. Practical Pharmacy. 7. Medicine. 8. Surgery. 9. Midwifery. 10. Forensic Medicine.

II.—AS TO THE METHOD OF CONDUCTING THE EXAMINATIONS.

1. That they should be both oral and in writing.
2. That not less than two Examiners, or one Examiner with an Assessor, should be present at every oral Examination.
3. That the oral Examinations should be so far public as to be open at least to the Medical and Surgical Graduates, or Members of the Examining Body.
4. That the questions to be answered in writing should be so numerous, and embrace such a variety of the details of each subject, as may adequately test the proficiency of the candidate; and that they should be

submitted to the whole body of Examiners for consideration and revision, if desirable, before being proposed to the candidates.

5. That the written answers should be submitted to more than one of the Examiners.
6. That Practical Examinations should be held in all the subjects in which they can be employed.
7. That excellence in one or more subjects should not be allowed to compensate for failure in others.
8. That if a candidate be rejected for failure in any one subject, he should be re-examined in all.

III. That Examiners should only be elected for definite periods, with power of re-appointment.

G. E. Paget, Chairman.

The report was received and entered on the minutes.

After a considerable discussion upon various questions contained in the report, the following resolutions founded upon it were adopted:—"That the General Medical Council are of opinion—1. That it is desirable that the different licensing bodies should combine their examinations, when this is practicable, so as to secure that the knowledge of every practitioner whose name appears on the register shall have been tested in all the subjects of professional education which the Council has determined to be essential—viz.: 1. Anatomy. 2. General Anatomy. 3. Physiology. 4. Chemistry. 5. Materia Medica. 6. Practical Pharmacy. 7. Medicine. 8. Surgery. 9. Midwifery. 10. Forensic Medicine." Upon the second resolution—"As to the method of conducting examinations"—the following recommendations were discussed *seriatim*:—"1. That they should be both oral and in writing. 2. That not less than two examiners, or one examiner with an assessor, should be present at every oral examination. 3. That the oral examinations should be so far public as to be open, as far as practicable, to the medical and surgical graduates, or members of the examining body. 4. That the questions to be answered in writing should be so numerous, and embrace such a variety of the details of each subject, as may adequately test the proficiency of the candidate; and that they should be submitted to the body of examiners or governing body for consideration and for revision, if desirable, before being proposed to the candidates. 5. That the written answers should be submitted to more than one of the examiners. 6. That practical examinations should be held in all the subjects in which they can be employed. 7. That excellence in one or more subjects should not be allowed to compensate for failure in others. 8. That if a candidate be rejected for failure in any one subject he should be re-examined in all."

The third resolution, amended on the suggestion of Sir D. J. Corrigan—"That examiners should only be elected for definite periods, and be eligible for re-election," was then agreed to, and the Registrar was directed to forward these recommendations to the various licensing bodies.

Dr. Alexander Wood moved "That the Registrar be directed to draw up, in the usual form, the recommendations and opinions of the General Medical Council with regard both to the preliminary and professional examinations; and that copies be issued to the various licensing bodies."

This motion was seconded by Dr. Andrew Wood, and carried without discussion.

On the motion of Dr. Paget, seconded by Dr. Fleming, it was unanimously resolved—"That copies of the (1) Observations of the Licensing Bodies upon the Report of the Committee, 1867, of the Medical Council on the Visitations of Examinations; (2) the Reports of Visitations of Examinations which have been made since the last session of the Medical Council; and (3) the Report of the Committee thereon, entered in this day's Minutes, be sent to the various licensing bodies, together with the Resolutions of the Medical Council thereon."

The report of the Committee of last year upon the same subjects was, on the motion of Dr. Fleming, seconded by Dr. Alexander Wood, dropped.

The last subject brought under the consideration of the Council was the report of the Committee on returns from the licensing bodies of Professional examinations and their results, and on the registration of students for the year 1867.

1. The Committee beg leave to present a table, compiled from the returns, according to Recommendation 6, sec. v. of the Recommendations of the Council, 1866 (vol. iv. p. 311)—viz., that returns from the licensing bodies in Schedule (A) be made annually, on January 1, to the General Medical Council, stating the number and names of the candidates who have passed their first as well as their second examinations, and the number of those who have been rejected at the first and second examinations respectively:—

Table for 1867.

Totals		1169	1504	148	379	300	17

* Three of this number were examined in Physiology only.

The Council will observe with satisfaction that this year the table comprises returns from the whole of the nineteen licensing bodies without exception, and the Committee are not aware that any person has entered upon the study of the Profession without having been previously registered as a student in Medicine.

2. The number of students registered during the year 1867 is as follows:—

In England	457
In Scotland	258
In Ireland	212
Total	927

According to the Medical Students' Register, every person registered during the year 1867 has passed the required preliminary examination (No. 2 of Recommendations on Registration of Medical Students), but your Committee have been informed that in Ireland a good many students have been allowed to enter upon Medical study on condition of their passing an examination in general education before the end of their second year of Medical study.

The following five paragraphs show the present state of things in reference to this point:—

The King and Queen's College of Physicians of Ireland holds no preliminary examination themselves, every candidate for their qualifications, with very rare exceptions, having already passed elsewhere an examination in preliminary education.

With the Royal College of Surgeons of Ireland the rule is to require candidates to pass a preliminary examination before commencing Medical study; the exceptions to this rule are very few.

The Apothecaries' Hall requires in all cases the preliminary examination to be passed before Medical study is begun.

With regard to the University of Dublin, it appears that the Act of Parliament which sanctions the matriculation of Medical students without any previous examination in Arts, is practically a compulsion on the University to admit to the advantages of the Medical school students who do not intend to enter on the ordinary studies in Arts. This provision of the Act is not approved of by the University, but cannot be said to affect any persons who take degrees in Medicine, as such degrees are conferred on those students only who have previously graduated in Arts.

The Queen's University in Ireland does not require the preliminary examination as an antecedent to the commencement of Medical Study.

The Committee would suggest to the Council that the Registrar be requested to address a letter to those licensing bodies in Ireland which do not require the preliminary examination to be passed before Medical study is begun, representing that throughout England and Scotland a complete uniformity has been brought about by the adhesion of the licensing bodies to the recommendation of the General Medical Council in this respect, and that it is highly desirable that students in all the three divisions of the kingdom should be placed on the same footing, making a rule absolute requiring preliminary education and examination to be really preliminary to Medical study.

3. In regard to the resolution of the Medical Teachers' Association referred to the Committee—viz., "That in the opinion of the Association, the registration of the metropolitan students of Medicine should be performed at one office only"—the Committee beg leave to say that the Council has only one office of registration for metropolitan students—viz., that at No 32, Soho-square—and to this no student is obliged to go, as the object can be entirely effected by correspondence.

The registration is of two facts only—viz., that a pupil has passed his preliminary examination and has commenced his Professional study. The Medical Council have no authority over the licensing bodies as to the registration of students, and the internal regulations frequently include many more facts than the above, and some of these are registered at different periods of Professional study.

4. The Committee have had before them and considered the letter of Dr. Edwards Crisp "on the increase of half-qualified Practitioners since the passing of the Medical Act." They think it may be advantageous to have an official analysis, under the care of the Registrar of the General Medical Council, of the *Medical Register*, such as that made by Dr. Crisp, and which should appear on the Minutes of the Council. They are of opinion that the Council has no power under the Medical Act to interfere with the number and kind of qualifications that Practitioners choose to obtain, and that the consideration of Dr. Crisp's "Representative Faculty of Medicine" does not come within the scope of duty of this Committee.

5. The Committee have to recommend to the Council that to the list of preliminary examinations, recognised by the General Medical Council, be appended the names of those examinations which, by the Branch Councils, have as special exceptions been admitted. (No. 9.—Regulations as to Registration of Medical Students.)

Dr. **Embleton**, in reading the report, said there were several inaccuracies, which it would be necessary to correct before it was entered on the minutes.

On the motion of Dr. **Embleton**, seconded by Dr. **Wood**, it was unanimously resolved that this report be received and entered on the minutes.

Dr. **Embleton** then moved—"That the registrar be requested to address a letter to those licensing bodies in Ireland which do not require the preliminary examination to be passed before medical study is begun, representing that throughout England and Scotland a complete uniformity has been brought about by the adhesion of the licensing bodies to the recommendation of the General Medical Council in this respect, and that it is highly desirable that students in all the three divisions of the kingdom should be placed on the same footing by the Irish licensing bodies using every means to obtain the necessary powers to enable them to require that preliminary education and examination shall be really preliminary to medical study."

The motion was seconded by Dr. **Alexander Wood**.

Sir **D. J. Corrigan** said he must object to consider any resolution founded upon a report which was a tissue of errors from beginning to end, and which the Council had had no opportunity of considering in its existing form, Dr. Embleton having made various important alterations and additions not contained in the printed copy, and proceeded to criticise the various inaccuracies of the report, and urged that at the present late hour (six o'clock), it was necessary the entire matter should stand over for full discussion next year.

Dr. **Alexander Wood** must say that Sir D. Corrigan's speech bore very little upon the motion; and it reminded him of certain animals which, when closely pursued, were said to eject a black liquid to conceal themselves. In the same way Sir D. J. Corrigan, when he found the body he represented was closely pressed, had ejected a considerable amount of irrelevant matter to hide its imperfections. The Council was asked not to adopt the report, but to convey the expression of opinion contained in the motion to the licensing bodies, and he challenged Sir Dominic Corrigan and all the Irish professors, with all their talents, to educate properly a medical student whose mind had not been previously prepared by preliminary examination.

FIRST REPORT OF THE COMMITTEE ON STATE MEDICINE.

The following *interim* report was read :—

"The Committee on State Medicine beg leave to report to the Council that, having carefully considered the resolution of the Council by which the committee was appointed on June 27, 1868, they have decided with a view to presenting a more complete report at the next session of the Council, on taking evidence from various persons having special knowledge of the subject referred to the committee."

Replies were then ordered to be sent to the secretaries of the Medical Teachers' Association and Dr. Edwards Crisp in the following terms :—

"That a letter be addressed by the Registrar to the secretaries of the Medical Teachers' Association to the effect that the Council has only one office of registration for metropolitan students—viz., that at No. 32, Soho-square—and to this no student is obliged to go, as the object can be entirely effected by correspondence. The registration is of two facts only—viz., that a pupil has passed his preliminary examination and has commenced his professional study. The Medical Council have no authority over the licensing bodies as to registration of students, and the internal regulations of those bodies frequently include many more facts than the above, and some of these are registered at different periods of professional study.

"That a letter be addressed by the Registrar in answer to Dr. Edwards Crisp's letter 'On the increase of half-qualified Practitioners since the passing of the Medical Act,' to the following effect—viz., that it may be advantageous to have an official analysis, under the care of the Registrar of the General Medical Council, of the Medical Registrar, such as that made by Dr. Crisp. That the Council has no power under the Medical Act to interfere with the number and kind of qualifications that practitioners choose ; and that the consideration of Dr. Crisp's 'Representative Faculty of Medicine' does not come within the scope of duty of this committee."

Votes of thanks were then unanimously accorded to the Treasurers of the Royal College of Physicians (with a gratuity of twenty guineas to the resident officials), Dr. Andrew Wood (Chairman of the Business Committee), and the President.

The **President**, in acknowledging the vote, said: I beg to thank the Council for this compliment that is now offered me. I wish my services had been more efficient than they have been, but I have done my best, faithfully and impartially, to execute the duties entrusted to me. I feel extremely grateful for the manner in which every member of the Council has received my services. At the commencement of this session I ventured to suggest to the Council that my term of office was coming to a conclusion, and that I was very anxious that the members of the Council should confer together as to the time when it would be most convenient that I should vacate my office, and also as to who might be the best person to succeed me. I am very glad to learn that the Council has had a private conference, and from the Chairman of that private conference I learn that it will be for the convenience of the members of the Council, and for the good of the conduct of the business of this Council, that I should offer my resignation at the termination of this session, as I propose to do. From a communication that has been made to me by the chairman of that private conference, I find another circumstance has been mentioned, which is, of course, most highly flattering to me, and most gratifying to my feelings—namely, that if I resign my office into your hands, the Council might be disposed to re-elect me to such a distinguished honour. Gentlemen, I assure you I almost hesitate even to allow my name to be proposed again to fulfil the arduous and responsible duties of the President of this Council. For I do assure you, that although I occupy what I consider a post of honour, and one which I highly value, yet, at the same time, my position is by no means always a bed of roses. I find very great difficulty in performing my duties here to my own satisfaction; and of course they must be very often imperfectly and unsatisfactorily performed to yourselves. But it is not during the session, alone, that I feel my duties arduous and responsible; it is much more during the intervals between the sessions, when a great deal of responsibility devolves upon me personally. It is true that from time to time I have the great advantage of conferring and consulting with the eminent men whom you have elected upon your Executive Committee; but that can only be twice or thrice in the year, and in the intervals between the meetings of the Executive Council I am left very much to my own resources, and am obliged to assume a very considerable amount of personal responsibility. It is then that I feel my greatest difficulty, and I should be wrong —I should not be doing that which is agreeable to my own feelings—if, before quitting this chair, I did not say that I really could hardly have supported those responsibilities, or performed my duties to my own satisfaction in those intervals, unless I had had the great advantage and comfort of being able to rely upon the wisdom and the knowledge of business and the power and perfect independence of spirit of a friend who was once associated with me as treasurer here, and who still occupies that important office. There is another duty which devolves upon me as President which must necessarily fall upon any other President—that is to say, a great deal of correspondence devolves upon me in the intervals between our sessions. I do not think any gentlemen sitting round this table is aware of the amount of correspondence which falls upon your President, both with the Government, the Medical bodies, the colonies, and private individuals. A great many of those letters, in reply, require consideration, care, thought, delicacy, and careful wording: and here I should be sorry to quit the chair without acknowledging my great obligations to the amiable and accomplished gentleman who fills the office of Registrar. His support, advice, and assistance in these matters of correspondence are really most valuable, and I am greatly indebted to him for his services. Gentlemen, I have nothing more to say but to renew my acknowledgment for the past, and to say that, should your choice fall upon me for the future, I will endeavour to perform my duties to the best of my ability. But should it fall upon me again to be elected to this dignified office, I wish it to be distinctly understood that I cannot undertake the duties for the five years, and that I only accept them until such time as you can among yourselves find a successor whom you think worthy to occupy this chair. With these observations I retire from you, and wish you God-speed for another year.

The President then retired from the Council, when he was re-elected unanimously amidst loud and prolonged cheering, and the Council concluded the session of 1868, soon after seven P.M., having sat this day more than seven hours.

Correspondence.

MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The battle of medical reform has now been fairly begun. The Medical Council has refused to accede to the wishes of the profession so far as even "to consider the propriety of attempting to obtain a change of constitution." No other result was to be expected—nor, to my mind, even to be desired. No urging of the question by the Medico-Political or British Medical Associations could so effectually arouse the attention of the profession to their own interests in this matter as will be done by this refusal of the Medical Council to entertain the subject. Let us not fear the battle, the result cannot be doubtful; without a battle, we might have an ignominious treaty, we could not secure a splendid victory. The Council, have, however, very distinctly indicated to us what our next step in the matter must be, namely, an application to Parliament, based upon the interests of the public; for a low class of practitioners evidently injure the public by their practice even more than they injure us by their competition.

Such an appeal to Parliament we must bring forward as soon as we have a practical organisation in working order to carry it out.

Sir Dominic Corrigan has nobly redeemed his promise given to the Medico-Political Association, that he would support this question when it should come before the Council. The profession ought to use every endeavour to place him in Parliament as the advocate of their interests, when this measure may be brought before the House. Nobody ever supposed that the Council could alter its own constitution; the question was would they, in the interests of the profession and of the public, seek from Parliament such an alteration as the profession indicated as necessary. This, they have refused to do for us; we must now do it for ourselves. But their refusal will have no other effect than to arouse the attention of the profession and the public to the question, and to give time and opportunity for the "education" of both as to their true interests in the matter.

It has been urged in the Council that our representatives would neglect higher questions, in order to complain of the insufficient remuneration of the profession; the best answer to this is the fact that the profession has already grasped the idea that its insufficient remuneration is to be effectually remedied only by going back to the highest question of all—namely, its own representation on the Council. And hence, we may fairly argue that our representatives when seated there, would bear in mind that they were sent there to deal with *principles*—*i.e.*, with the higher questions, and not with details, and that hence they would strike boldly at the root of the evil, which the Council at present handle so tenderly, but which we instinctively recognise as excessive competition, caused by a low standard of qualifications both preliminary and professional, which again is owing to the rivalry of the corporations for licensing fees, and the inability of one to raise its standard for fear of sending three-fourth's of its candidates elsewhere. This is the root of the evil, and I have elsewhere proposed to deal with it by making the emoluments of the colleges quite independent of the number of candidates passed by them. My views on this point, and on the representation of the registered practitioner, the Council of the College of Surgeons have pronounced "Utopian, and in advance of the age," it remains to be seen whether the profession and the public, in whose interest they were proposed, will regard them in the same light. One thing is certain, that unless the root of the evil is dealt with in some such manner as this, our remuneration and status will remain what they are at present. Why does Dr. J. C. Reid, in the Morpeth Union, get only £10 a-year, as reported in your last, for attending to a population of 3000? Why does Dr. Gill, in the same county, get only £6 for a district of 21,000 acres? Why is a similar scale the rule all through Northumberland? Because there are several other men ready to come forward at the same tariff, and take their private practice from them if they refuse such a scale. How were the committee of the Ashford dispensary district, near Wicklow, able the other day to reduce their salary from £100, which their late officer was paid, to £85? Because even at £85 there were several men to apply for the post. This excessive competition in the profession must be put an end to, and the only legitimate way to do it is by enforcing a really high standard of preliminary and professional education. This is the "higher question" with which our representatives must boldly deal, when we shall have won our first battle of representation in the Council, and thus obtained a standing ground for our next move.

The profession seems to have been strangely hoodwinked by Dr. Paget's statement that his constituency numbered 5400 electors. Why, these are all *non-professional electors*, mere Masters of Arts of Cambridge University; the total number of *graduates in medicine* of Cambridge University in 1867 was only 142. Should these wish to give a vote adverse to the choice of the senate, the latter body can, it is true, overpower them by influencing the votes of the non-professional 5258; but these latter electors take no further interest in us, or our concerns. Such a fallacy as this cannot be allowed to pass unnoticed.—I am, dear sir, yours truly,

ISAAC ASHE, M.B., T.C.D.,
Gen. Sec. for Ireland, Medico-Political Association.

Warrenpoint, July, 1868.

THE PHARMACY BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your report this week of the discussion on the above bill, in reference to its extension to Ireland, in answer to Dr. Leet's concise and able protest, Dr. Aquilla Smith stated that, since the year 1855, Pharmacy has greatly degenerated in Ireland, and since the passing of the Medical Act in 1858, it has become so low that a physician would have great difficulty in getting a prescription made up by an apothecary in Ireland. Does Dr. Smith mean that they are too proud to engage in pharmacy, being general medical practitioners, or that they are incompetent to perform the duty for which they prepared for years? In regard to their unwillingness, I will merely refer Dr. Smith to the daily advertisements from medical halls both in Dublin and the provincial towns. [illegible] they are incompetent, which I am far from allowing, I don't think that Dr. Smith's remedy—allowing druggists to compound (for, in that class, chemist is only a name)—would lessen the difficulty. The accidental poisoning statistics of England, compared with that of Ireland, are, I think, suggestive enough.

Apologising for trespassing so much on your valuable space, I am, sir, yours respectfully,

George P. Atkins.

Dublin, July 9, 1868.

IODIDE OF SULPHUR IN THE TREATMENT OF "PORRIGO FAVOSA."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I have submitted the following cases for publication in your valuable journal, thinking that they might prove of interest, by illustrating the beneficial action of iodide of sulphur in the treatment of a most inveterate skin disease, viz., *Porrigo Favosa*, commonly known as scall head.

John Riley, æt. 18 years, William Riley, æt. 7 years, and Patrick Riley, æt. 5 years, three brothers, were admitted into the Skibbereen Workhouse Hospital, February 27th, 1868, suffering from porrigo favosa in its most aggravated form. The eldest had been affected for eight years—the second for six years, and the youngest for about twelve months; their heads were covered with the mouldy-looking honey-combed crusts peculiar to this disease. In some places where the crusts had fallen off, the integument presented a red-glazed looking appearance, studded here and there with yellow pustules, and totally devoid of hair; their general health was good, and neither of them any indication of a scrofulous diathesis.

During two months succeeding their admission into hospital various plans of treatment were adopted, such as the use of sulphur and citrine ointments, corrosive sublimate and nitras argent solutions, and also painting the diseased surface from time to time with tinct. iodine. Temporary relief was occasionally afforded, but the disease invariably returned in as bad a form as ever. On the 21st May, the following treatment was adopted, and produced quite unexpectedly a speedy and permanent cure. After softening and detaching the crusts by the application of linseed-meal poultices, an ointment composed of iodide of sulphur, ʒi., adeps. ℥iss., intimately mixed together, was ordered to be well rubbed into the diseased patches night and morning. This treatment was continued regularly, and on June 10th, a fortnight after it had been first adopted, a marked improvement had taken place; the formation of fresh scabs was arrested, the red patches of skin had almost disappeared, and hair began to grow from several portions of the scalp which were previously bald.

The three patients were discharged cured from hospital, June 30th, as there were no indication whatever of a return of the disease, and their heads were uniformly covered with hair.

If the iodide of sulphur treatment should prove equally beneficial in most other cases of porrigo, it would supply a very simple means of arresting this disease, instead of having recourse to the internal use of arsenic and iodine, and the application of caustic and poisonous lotions to the skin: the use of which remedies in the case of children, is attended with considerable risk, especially in country districts where one must often rely upon ignorant and careless people to administer them, and therefore must be very guarded how he entrusts to the] hands of such persons medicines that might prove fatal, if not carefully given in the prescribed dose, or not used as otherwise directed.

It is not many years ago, before the true nature of porrigo was discovered, when the barbarous plan of applying pitch caps to the scalp was adopted on the Continent, and in some parts of Ireland where the disease was tolerably prevalent. These pitch caps consisted of strips of stout calico, spread with Burgundy pitch, or some other adhesive material, and after being firmly applied to the scalp, they were forcibly torn off in a direction contrary to the growth of the hair, so as to tear the hairs out from their roots; this plan was adopted under the erroneous impression that the disease originated in a morbid condition of the hair bulbs, and not unfrequently either scalped the victim or produced death. In this case, as in many others, microscopic and chemical research have come to the aid of medicine. The microscope has determined that porrigo favosa depends on the formation of low vegetable growths of a fungous nature (achorion schönleinii) in the deeper layers of the epidermis and upon the surface of the cutis, attacking the hair follicles, and causing alopœcia in most cases. Chemical researches have discovered that sulphurous acid in a fluid or gaseous form, and the sulphites, especially the hyposulphite of soda, and the compound resulting from the union of iodine and sulphur, have a sort of special capacity for destroying the vitality of such vegetable organisms when they come in contact with them, and we thus have a rationale to follow out, when applying these remedies to the treatment of porrigo favosa, instead of having recourse to haphazard modes of treatment which generally produce more harm than good, and invariably aggravate the sufferings of those who are the victims of the disease under consideration.—Your obedient servant,

Daniel Donovan, Jun., M.D.

Skibbereen, Co. Cork,
3rd July, 1868.

◆

Medical News.

The Public Health.—We extract the following from the weekly returns of the Registrar-General:—"In the week that ended on Saturday, July 4, 4620 births and 3180 deaths were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 25 per 1000 persons living. The annual rate of mortality last week was 25 per 1000 in London, 25 in Edinburgh, and 17 in Dublin, 20 in Bristol, 22 in Birmingham, 26 in Liverpool, 33 in Manchester, 25 in Salford, 35 in Sheffield, 24 in Bradford, 25 in Leeds, 25 in Hull, 26 in Newcastle-upon-Tyne, and 26 in Glasgow. The mortality from diarrhœa, principally infantile, showed a considerable increase in most of the large towns last week. Of the death rates from all causes, 6 per 1000 resulted from this cause in Manchester, 5 per 1000 in London and Salford, and 2 per 1000 in Liverpool. The excessive rate in Sheffield was due to 15 more deaths from small-pox, in addition to a considerable mortality from measles and diarrhœa. The deaths registered in London during the week were 1516. It was the twenty-seventh week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1315. The deaths in the present return exceed by 201 the estimated amount, and are more by 62 than the number recorded in the preceding week. The deaths from zymotic diseases were 577, the corrected average number being 395. Nine deaths from small-pox, 55 from measles, 36 from scarlatina, 11 from diphtheria, 49 from whooping-cough, 46 from fever, 286 from diarrhœa, and 19 from cholera or choleraic diarrhœa were registered. The mortality from diarrhœa exhibits a considerable increase. In the week which ended the 6th of June, the deaths from diarrhœa were 27, in the three following weeks 31, 66, and 171 persons died, and last week the deaths recorded were 286. The deaths from fever were at the annual rate on 10,000 living of 4 in West London, 7 in North London, 9 in Central London, 13 in East London, and 5 in South London. In calculating these results the deaths in the London Fever Hospital have been referred to the districts from which the patients were brought. At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 30·023 in. The barometrical reading increased from 30·05in. on Sunday, the 28th of June, to 30·21in. by 9 A.M. on Monday, the 29th of June; decreased to 29·81 by 3 P.M. on Friday, the 3rd of July, and was 29·88in. by the end of the week. The mean temperature of the air in the week was 61·6 deg., which is 0·4 deg. above the average of the same week in 50 years (as determined by Mr. Glaisher). The highest day temperature was 84·3 deg. on Friday, July 3rd. The lowest night temperature was 47·8 deg. on Tuesday, June 30. The entire range of temperature in the week was, therefore, 36·5 deg. The mean of the highest temperatures of the water of the Thames was 66·7 deg.; that of the lowest was 65·4 deg. The difference between the mean dew point temperature and air temperature was 10·6 deg. The mean degree of humidity of the air was 68, complete saturation being represented by 100. Rain fell on Saturday, July 4, to the amount of 0·01in. The general direction of the wind was N. and N.N.E. Ozone was observable on four days of the week. Since Friday, the 29th of May, when rain fell to the amount of 1·08in., to Saturday, the 4th of July, rain has fallen on only six days, amounting in the aggregate to 0·47in. in 36 days. According to a return furnished by the engineer of the Metropolitan Board of Works the daily average quantity of sewage pumped into the River Thames at the Southern Outfall Works, Crossness, was 39,700,733 gallons, or 180,379 cubic metres, equivalent to about as many tons by weight."

University of Cambridge.—Natural Science Scholarship.—Mr. C. Fox has been elected to the Natural Science Scholarship (value £60 a-year), at St. Peter's College. Mr. Fox is a student at University College. The examination was in Botany, Comparative Anatomy, and Chemistry.

Registration in Scotland.—The medical profession of Scotland are protesting against what is an undoubted grievance. When the Registration of Births, Deaths, and Marriages Act was passed in England in 1835, the medical men of England were solicited to render their services gratuitously for State purposes, and for behoof of the public, by forwarding to the registrars certificates of the causes of death in cases which had come under their professional notice. As a matter of course this is always done, but it is not done compulsorily, but as a certain courtesy which the doctors pay to the nation. In 1854 a similar Act came into operation in Scotland, but for some unaccountable reason (for the English Act has always worked without any hitch) power was given by it to compel the practitioners to grant professional certificates of the causes of death, under the threat of the infliction of serious penalties, recoverable at the instance of the criminal officers of the Crown. The distinction is a very invidious one, and utterly uncalled for. The medical gentlemen of Scotland have never objected to give their services gratuitously for the public interest; but what they object to is the exaction of such services compulsorily, or under penalties for nonfulfilment. It is justly regarded as a slight cast upon the profession in Scotland, and the present time, when medical votes are of some value to university candidates, is, with considerable sagacity, thought to be a seasonable one for getting it removed. Some years ago, when Mr. Moncreiff held the office of Lord Advocate, an attempt to this end was made, by means of a clause in a bill which was under the charge of Sir William Dunbar, but the medical applicants were not successful in convincing the official gentlemen of the hardship under which they laboured. The effort has been renewed within the last few days under better auspices. At a meeting of the faculty in Glasgow, a memorial was drawn up to the Lord Advocate, pressing the matter upon his attention. To this a favourable answer has been received, but Mr. Gordon is compelled to confess that legislation to give effect to it is impossible this session. We may tender a word of advice on the subject to that portion of the profession in Scotland who are members of the united constituency of Aberdeen and Glasgow Universities. They have as candidates for their suffrages the present Lord Advocate, and the gentleman who, in the event of a change of government, is certain to be his successor. Let them make assurance doubly sure, by exacting a pledge from both candidates that each will make it his business to abolish with all speed this humbling distinction.—*London Scotsman.*

Sewage Experiments at Tottenham.—Last week experiments on the purification of sewage by means of a particular preparation of alum, according to Mr. Lenk's process, were made at the sewage works of the Tottenham Local Board of Health. A tank measuring about 50 ft. in length by 20 in breadth, was filled with 26,000 gallons of sewage, very black in appearance, and extremely offensive in smell. Forty-six gallons of the purifying "essence" were then sprinkled over the surface of the fluid by means of a hydropult, and afterwards stirred in by the aid of a wooden apparatus roughly improvised for the purpose. The fluid was then allowed to settle, and the action of the essence was seen in the precipitates. In about ten minutes, and at intervals afterwards, bottles were plunged into the deepest portion of the fluid, and on being brought to the surface and examined, the contents were fluid, though slightly blue. In half an hour the whole body of the sewage was much changed. The cost of this process is said to be trifling. Experiments were also made to contrast the alum process with that in which lime is employed. The subject will receive further elucidation by rigid chemical tests. It is hoped that the solid portion will prove a valuable manure, while the fluid will be such as may be safely discharged into open streams.

On Sunday morning the body of a retired farmer in Devon was found lying in an orchard fearfully mutilated. The deceased placed the muzzle of the gun to his ear, and by the use of the string had discharged it, thereby causing instantaneous death.

NOTICES TO CORRESPONDENTS.

Proofs reaching authors in England on or before Friday morning are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper only.

Mr. A. Drew, Brighton.—We have still a few copies of February 19th on hand. The two previous numbers are out of print. The annual subscription is 21s. 8d., post free, in advance.

Dr. T. S.—You will find the subject mentioned in another part of the paper.

Dr. Kirby is thanked for his note.

Mr. J. T., Manchester.—The back numbers from January 1st, with the exception of two "out of print," will be forwarded to New York, as requested, in the course of the present week. You will please remember, that the postage to the United States has recently been doubled. The postage per copy is now 2d.

Mr. W. Carrick, Crofts.—Your request has been attended to.

◆

BIRTH.

Watson.—June 24th, at West-green, Tottenham, the wife of William Tyndale Watson, M.D., of a son.

Advertisements.

NOTICE TO ADVERTISERS.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0 3s. 6d.
Per line afterwards	0 0s. 6d.
One-quarter page	1 5s. 0d.
Half "	2 5s. 0d.
One "	4 0s. 0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the Office, on Saturday, by Three o'Clock.

Queen Anne-street, Cavendish-square, London.—A very desirable Professional residence, having 4 good reception rooms; 8 bed-rooms; good office, and capital stabling, completely furnished; all in excellent condition—held at a very low rental—to be sold on most advantageous terms. Particulars of Messrs. Rae and Curtis, 14, Langham-place (next the Langham Hotel).

THE MEDICAL PROFESSION.

THE ALBERT LIFE ASSURANCE COMPANY. Established 1838—Annual Income £350,000, accepting healthy and invalid lives, is prepared to enter into special and liberal arrangements with members of the Medical Profession acting as private Agents of the Company.—Apply to the Secretary, FRANK EASUM, at the Chief Office, 7 Waterloo-place, Pall-Mall, London.

CONVERTIBLE OTTOMANS FOR CENTRE OF ROOMS,

To form two Settees and two Easy Chairs, a great improvement on the ordinary Ottoman. Only of

A CASE OF COMPOUND FRACTURE OF FRONTAL BONES, WITH FRACTURE OF CLAVICLE AND ACROMION.

UNDER THE CARE OF MR. ROBERTS, SURGEON.

(Communicated by HENRY B. DOW, M.D.)

TOM RICHARDS, aged 14, engaged as farm-labourer, was, on September 25th, 1867, driving some horses into a field, and happening to strike one with his stick, it immediately kicked, one hoof striking him on the right shoulder, fracturing clavicle and acromion, the other falling edgewise on the forehead, fracturing both tables and exposing dura mater. On my arrival, two hours after the accident, found him partially insensible and extremely weak, the loss of blood having been excessive, the supra orbital artery being wounded. A piece of bone, rather larger than a sixpence, had been forced on to the dura mater, causing slight compression of the brain. I immediately secured the artery, and with the aid of forceps and elevator removed the depressed bone, cleansed the wound, and applied simple water dressing. The nervous irritability was so great as to preclude the reduction of the fractured clavicle and acromion, the limb was placed in a comfortable position, and evaporating lotions applied. A gentle aperient was administered.

September 26th.—Passed a tolerable night but is very feverish, wound looking healthy; their is great intolerance of light and noise. Effervescing salines administered, and the lotion continued to the shoulder.

27th.—Doing tolerably well, had some refreshing sleep, and took a little nourishment; fleshy part of wound commencing to slough slightly, water dressing still applied. Nervous system still too much disturbed to admit of reduction of the fractured bones, so the limb was slightly shifted to prevent union, and evaporating lotion continued.

28th.—Improving.

29th.—Much fever, wound sloughing and discharging unhealthy pus mixed with ipiculve of bone; poultices to take the place of water dressing, effervescing salines to be continued, and perfect rest and quiet enjoined, the intolerance of light and noise being present in a marked degree.

30th.—Febrile symptoms diminishing, and there is decided improvement, wound discharging freely. There is great swelling and discolouration of shoulder, but little pain; it was again shifted, it being still not thought advisable to attempt reduction.

October 1st.—Still improving.

2nd.—Allowed to be conveyed home, about two miles.

3rd.—No bad symptom has arisen from his removal. Wound still discharging unhealthy pus, and symptoms of necrosis of surrounding bone becoming apparent.

4th.—General health improving, febrile symptoms having almost entirely disappeared. Considered that I was now justified in attempting reduction of the fractured bones, which was satisfactorily accomplished in the ordinary manner, with but little pain or inconvenience to patient.

6th.—Pieces of bone of various sizes are now being discharged with pus, which is excessive, and there is every indication of a large surface of surrounding bone becoming detached. To have good nourishing diet and wine.

8th.—Wound above and below the more serious injury commencing to heal.

8th to 25th.—Doing well; no bad symptoms; general health improving, but several pieces of bone of various sizes have exfoliated; satisfactory union of fractured clavicle and acromion has taken place.

October 28th to November 7th.—Complains of headache; health not so good, there is dullness and loss of appetite. On examining wound, which has not been seen for a day or two, a large amount of fungus is seen to have sprung up, which, on removal, exposed a piece of bone, which, taking into consideration the altered state of health and head symptoms, I decided on removing, and did so with the aid of forceps and elevator. It was about one and a quarter inches in length, and two-thirds of an inch in breadth, and beneath it the dura mater was exposed to that extent. Cold water dressing applied, perfect rest and quiet enjoined, and a brisk aperient administered.

November 8th.—Again improving.

9th.—The removal of the necrosed bone is attended with marked success, the head symptoms have entirely disappeared, and general health rapidly improving. The splints and bandages removed from the shoulder, which has resumed its former shape and power in every respect.

November 9th to December 9th.—During this time the progress is very satisfactory; less discharge and more healthy; all the diseased bone appears to have come away, and the wound commencing to fill up, whilst his general health is good.

December 9th to January 9th, 1868.—Wound steadily and gradually healing; nitrate of silver has been applied freely with great benefit, the granulations having been excessive.

January 15.—Wound nearly closed.

20th.—Patient discharged quite well. There is a depression over the inner angle of the right orbit large enough to admit the end of the finger. The amount of bone which exfoliated altogether measures about two inches square. The injured shoulder has completely resumed its former power and use.

UREA AND URIC ACID: THEIR RELATION TO HEALTH AND DISEASE.

By B. KELLY, M.D., L.K.Q.C.P.I.

When we take into consideration the great importance of the urine as an excrementitious liquid, and the part it has played from time immemorial in the pathology of numerous diseases, we may be somewhat surprised why its chemical composition and morbid qualities should have so little occupied, until a comparatively recent period, the attention of medical men. But if these portions of its study have been ignored and neglected, its reputed value as a *polychrest*, or useful remedy in sickness, has been recognized from a very remote antiquity.

Aristotle observed that when urine was retained unduly long in the bladder it emitted a stronger and more offensive odour after expulsion than when voided after the usual interval—a change which he justly attributed to the gross and viscid properties it thus acquired.

That the practice of *autouroposis* must have originated at an early period of the world either through the injunctions of physicians, or (which is not improbable) through the impulse and dictates of morbid imaginations, there cannot be a serious doubt; and yet disgusting and unnatural as the habit may have been, it was far exceeded in this respect by the internal use of *album græcum*, *meconium*, and the *sulphur occidentale* of Paracelsus. Celsus records the death of a favourite of King Autigonus, who died from the effects of drinking his own urine. This personage, according to the assertion of the great Roman physician, was notoriously intemperate. Pliny states that the suppressed menses are restored by the patients inhaling the warm fumes of fresh urine excreted by males under the age of puberty. The same author also believed, that as fullers were never troubled with the gout, and as stale urine was the liquid used by them in his time for scouring woollen fabrics and other articles of clothing, it must, therefore, be an appropriate, if not an effectual, remedy for the disease in question. But indeed there was scarcely a malady in the entire nosological catalogue against which the internal and external use of urine, fresh or stale, had not been deemed a sovereign specific from the days of Celsus and Pliny down to a century or two ago. The *autouroposis* of the ancients bids fair to be revived under a modified and less disgusting form by the modern application of certain saline constituents of the urine to the treatment of disease. Even in our own day, the besotted inhabitants of Kampschatka, who eat the Amanita Muscaria for the sake of its exhilarating influence upon the animal spirits, are wont, when the supply of the fungus is exhausted, to prolong its intoxicating effects by drinking freely of the urine they excrete after its use.

The first physician I find, in looking back through the long vista of time, who seemed to have had any definite knowledge of the chemical composition of the urine, is the renowned Dr. Willis. In his Treatise on the several kinds of urine, he gives a rough, but rather comprehensive, analysis of this liquid. According to him, it consists of a large quantity of serum, a less amount of salt, sulphur and earthy matter, and a small proportion of spirit. Van Helmont, the Flemish physician and chemist, who was a cotemporary of Willis', bestowed considerable attention on the physical characters of the urine. That, passed on rising in the morning, he called *urina sanguinis*, in contradistinction to the *urina potûs*, or that resulting from beverages.

It is quite unnecessary to allude here to the long and illustrious list of physicians of our own times who have rendered themselves immortal by their researches in the domain of urinary pathology, as their works and achievements are fortunately well-known to the Profession. But, as the subject is far from being exhausted, I have deemed it not unworthy or profitless to devote a few pages to the consideration of urea and uric acid, as two of the most important proximate principles of the urine, whether in a physiological or morbid point of view, and the relation they bear to the system in health and disease.

Urea.—This substance, which results from an oxydation, or species of slow combustion of the constituent elements of the tissues, is constantly found in the blood, urine, and other organic liquids of the economy, but more especially in the lymph and vitreous humor. It is excreted from the system exclusively by the kidneys and skin in a state of health; but in Bright's disease and other organic affections of the kidneys, the gastro-intestinal mucous membrane vicariously discharges the function of the disordered glands, and effects the removal of a large share of the noxious principle from the blood. Hence the vomiting and diarrhœa which not unfrequently accompany the more advanced and serious cases of albuminuria. These accidents, being in a measure critical of the disease, and curative in their tendency, ought never to be incautiously interfered with or suddenly checked.

Whether urea be obtained as a constant and natural product of the living body, or is fabricated in the laboratory of the chemist, its physical characters and elementary constitution are always the same. Dry urea contains no water of crystallization, and, being a quarternary compound, possesses all the well-known chemical instability of such substances. Whether hydrated or anhydrous, it is readily converted by stale or putrid mucus, or by any agents capable of acting as ferments, into carbonate of ammonia. It is dimorphous, that is to say, capable of assuming two distinct crystalline forms according as it is slowly or rapidly evaporated.

Urea is in its origin and essence purely excrementitious; and where, from any cause, it is suffered to accumulate in the blood, it invariably gives rise to alarming nervous accidents, as amaurosis, convulsions, paralysis, &c., which, if neglected, usually terminates speedily in death. It also occasionally enters as an active element into the pathogeny of serous inflammations.

The first liquid of the body which contains urea in largest proportion is the lymph. The lymphatic vessels, indeed, may be said to be purposely set apart for the special absorption and accommodation of this substance, in the same manner as the lacteals are for the imbibition and reception of the chyle. The more abundant the lymph, the more abundant, all other things being equal, will be the quantity of urea contained in it; and as the quantity of lymph increases up to a certain point in a state of abstinence, and as the individual, in such circumstances, feeds, so to speak, and subsists upon his own tissues, the proportion of urea necessarily increases, thus demonstrating the large amount of animal matter that was necessary to be consumed to supply the want of the customary food, and to keep the living machine in active motion. When abstinence, however, is prolonged to an extreme degree, so as to approach starvation, not only the serum of the lymph greatly diminishes, but its solid constituents, and notably the urea, decrease, yet not to the same extent as the watery portion of the humor.

The venous blood always contains a greater or less quantity of this substance in solution, which not only varies from one vein to another, but according as the subject of the experiment is in a state of repletion or one of abstinence. The amount of urea contained in the venous blood in the former case is relatively small, for the reason that the vessels are filled to turgidity and have barely power to support the column of blood circulating in them; while in the latter, the veins are comparatively empty and flaccid, and endosmosis of liquids with their soluble contents readily takes place through their walls. The left vena innominata contains a greater proportion of urea than all the veins of the body, from the fact that the greater thoracic duct empties its contents into the left subclavian previous to its junction with the internal jugular of the same side; next to this vessel, the brachiocephalic of the right side contains the greatest amount of urea, more especially when the lesser thoracic duct enters it. The renal veins, for obvious reasons, contain the smallest share, and yet they are never entirely free from it either in a diseased or healthy state of the kidneys.

As a greater or less quantity of urea is always found in the blood of the renal veins, it becomes a question to decide from what source it may be derived. There are only two points to which we can legitimately trace its origin; either it must have escaped the filtering process in the kidneys, and thus directly entered the capillaries of the renal veins; or it may have penetrated the coats of the latter from the substance of the glands in which it had been formed as an effete product of nutrition. The former view in all probability is the more correct, especially in presence of the anatomical fact that the organs in question are duly supplied with lymphatics, not very abundantly, it is true, but yet sufficiently so to effect the removal of the urea as rapidly as generated. In Bright's disease, however, and in acute nephritis, the quantity of urea carried off by the renal veins is almost as great as that contained in the renal arteries.

The arterial system always contains a larger share of urea both in health and disease than the veinous. When we take into consideration that, with the exception of the small quantity removed from the renal arteries, the entire mass of the urea centres here, we may well be surprised why an element so excrementitious in its nature, and so deleterious to the healthy functions of the economy when, from any cause, it has accumulated to excess in the blood, should circulate so freely in the arteries without producing any serious disturbance or perceptible change in the process of nutrition.

The existence of urea in large quantity in the vitreous humor was first verified by Millon, and has ever since puzzled scientific men to account for its presence in a secretion which is so very dissimilar to the urine both in physical and chemical characters. I have ventured to approach the vexed question, and to offer an explanation thereon, leaving it to others to judge of its correctness. We know that the vitreous humor being a permanent, recrementitial product of secretion is never absorbed, at least in no appreciable quantity, in the healthy state, but remains hermetically enclosed in the cavity of the eyeball. Possessing great viscidity and consistence, its endosmotic property is also very considerable. But as urea is formed in all the tissues of the body wherever blood-vessels and lymphatics are found; and as it is dissolved by the fluids which bathe and permeate these tissues, it must necessarily enter the vitreous humor; and as it cannot possibly escape unless the humor has undergone liquefaction, it must increase by gradual and constant accessions. How far its accumulation may be instrumental in producing or aggravating certain forms of blindness and impaired vision may become a fruitful subject of inquiry in future experimental research.

Uric Acid.—This substance resembles urea in being an organic product of nutrition, and in elementary constitution, but is entirely unlike it in its chemical affinities and reactions, as well as in physical characters. It is also unlike it in not being ever formed outside of the living system by artificial means. Besides forming stable compounds with soda, lime, potash, magnesia and ammonia by converting them, as the case may be, into alkaline, neutral, or acid salts; it is changed into alloxan and allantoin—the highest degrees, possibly, of oxydation, if we except alloxantine and parabanic acid, to which this principle is capable of being raised—the former by nitric acid, the latter by the peroxide of lead.

Uric acid, which in the human subject is always a morbid product when it exists in excess in the blood and urine, is a normal, excrementitious principle of tissue-metamorphosis in insects, birds, and reptiles. As the nitrogenous elements abound in the systems of these animals, and very little of the fatty or carbonaceous, we can reasonably account for the enormous quantity of uric acid and urates, and the extremely small proportion of water and carbonates excreted by them. In herbivorous mammalia, on the contrary, uric acid and the urates are never found as constituent elements of their urine in its normal condition; whereas urea, the alkaline carbonates and phosphates, are abundantly formed as natural products in their systems, and are copiously discharged in their urine. When, however, such animals are kept in a state of abstinence for a time varying from twenty-four to forty-eight hours, the alkalinity of their urine disappears, and, with it, its usual turbidity; the excreted liquid becomes limpid, and exhibits a decided acid reaction, owing to the presence of uric acid, and acid urates and phosphates contained in it. Claude Bernard accounts for this remarkable change in the physical characters and chemical constitution of the urine of herbivora during abstinence, by referring to a counterchange which ensues in the nature of their aliments—the animals, in such circumstances, living upon their proper tissues, thus becoming, for the time being, to all intents and purposes, carnivorous.

It is known that cold-blooded animals, as reptiles, whose respiration is very slow, abundantly excrete uric acid, either free, or in combination with alkaline bases, especially ammonia. From this it has been inferred that the formation of uric acid, whenever it occurs in the human subject, results from a deficient oxydation of the nitrogenous elements of the food and tissues. Cl. Bernard, however, warns us earnestly against accepting this theory, and cites, as an illustration, the example of birds, in whose systems uric acid is freely generated, notwithstanding that their respiration is extremely rapid. Here, truly, is a dilemma—how to reconcile a uniform and constant effect with conditions and causes so diametrically opposed. For my own part, I think that the conditions in question are not so conflicting as they seem. The respiration of reptiles, it is true, is very slow; but their circulation, also, is equally torpid; there is consequently an equilibrium established between both functions. In birds the contrary of this obtains; their respiration is very active, as is, also, their circulation; their blood, too, is extremely plastic from its great richness in coagulable principles, especially fibrine. The generation of uric acid takes place, as we know, with equal uniformity in both cases under apparently different circumstances. We cannot attribute its formation exclusively to an active respiration, nor yet to a slow, we must, therefore, look to other conditions and causes than those mentioned in order to solve, with any degree of satisfaction, so perplexing a problem.

I have already stated that the nitrogenous elements abound in the systems of insects, birds and reptiles, and that the carbonaceous or fatty matters are greatly deficient, or only exist as secondary, or accessory constituents. Hence the great quantity of uric acid and urates (all azotized products) normally formed and eliminated by them; whereas water and the carbonates are so extremely scant as only to amount to mere traces in their excrements. Let us look again to the sheep and ox, for instance, in whose bodies are usually hoarded up such great masses of fat, and what do we find? Neither uric acid nor urates are ever discharged by them as normal excrementitious products, while the alkaline carbonates and earthy phosphates are so abundantly excreted by their kidneys, that their urine may be well considered a saturated solution of these substances.

Like all other herbivorous mammalia, these animals are heated more by the combustion of their fat than by the oxydation of the nitrogenous principles of their compact tissues. The reverse of this obtains in birds and reptiles; not being furnished with the so-called calorifacient substances, or only so to a very limited degree, combustion of their solid structures, and, as a consequence, oxydation of their constituent elements, take place; and hence the marked disparity in the nature of their excrementitious products as compared with those of the above-named animals.

Uric acid being very sparingly soluble, requiring, as it does, 10,000 parts of water at 60° for its solution, it becomes an important question to decide why it should remain soluble in the blood and urine, not being spontaneously precipitated from the latter for many hours after emission, even when it exists in abnormal quantity, as in cases of gout and rheumatism. Heat, we know, is favourable to its solubility, but when once crystallized, elevation of temperature may be carried almost to the point of decomposing it without effecting anything more than its partial solution, unless the quantity of liquid employed bears an exaggerated proportion to the amount of acid to be dissolved. It is quite possible, however, that as fermentation rapidly takes place after expulsion of the urine, under certain morbid conditions, the more soluble urates become decomposed through the agency of new-formed acids (the lactic and acetic), the substance in question is precipitated, the liberated bases being converted into lactates and acetates.

The chloride of sodium, which always exists in greater or less quantity in the blood and urine, assists materially in keeping the urate of ammonia soluble in these liquids; but I am not aware that it exerts a similar influence over uric acid.

The urates, also, are remarkable for their slight solubility in water and the urine, and may be distinguished by this character from other saline substances with which they are usually associated, and with which, as a consequence, they might readily be confounded. They become more soluble by heat, and by the addition of alkaline carbonates and phosphates, which, without decomposing them, convert them from acid salts into neutral or alkaline urates.

Urea is a natural and constant product of nutrition in the human subject so long as the functions of the organism are performed with regularity and health; but when from any cause these are deranged, the urea ceases to be formed in normal quantity, and its place becomes occupied by uric acid and its compounds. Hence we find these substances in great abundance in remittent, intermittent, typhoid and other fevers, in rheumatism, gout, and in all acute and many chronic inflammations. According to Cl. Bernard, the urea also diminishes in the urine towards the last stage of inanition. This may be explained by keeping in view the well-established fact that in the early stage of abstinence the lymph and urea are increased in absolute and relative quantity, the system as yet being vigorous and not suffering from the depressing effects of actual starvation, the animal meanwhile feeding upon his own tissues. All this is changed when he has fallen into that state of utter debility consequent upon long-continued fasting. The circulation becomes slow and languid, and in this manner keeps pace with the retarded respiration; the surface is dry and rigid, the tissues in general grow atrophied, all the organic liquids of the body—blood, lymph, urine, &c., with their constituent proximate principles—are reduced to the lowest possible ebb, and evince a strong tendency to putrefaction, as well *in situ* as when withdrawn from the system.

Frerichs and Wöhler have found that when urate of potash had been taken into the stomach, the normal quantity of urea contained in the urine had increased. From this observation they were led to believe that the excess of urea was due to an oxydation of uric acid, which they therefore considered to be the mere exponent of the first step in the oxydation of azotized substances. M. Gallois, who repeated the same experiment, was unable to verify the result obtained by the German physiologists. On the contrary, he found that the quantity of urea usually voided in the twenty-four hours had sensibly diminished.

If oxydation is to be measured by the degree of heat evolved in the human system as in external combustible substances, we are forced to admit that the elements entering into the constitution of uric acid undergo a higher oxydising process than those of urea in the diseases mentioned. Chemical analysis of both these products confirms, I believe, the correctness of this deduction. The atomic composition of urea is thus represented:—$C_2\ H_4\ N_2\ O_2$; and that of uric acid—$C_{10}\ H_4\ N_4\ O_6$. We here see that uric acid contains oxygen in the proportion of 6 to 18, or one-third of the other equivalents; whereas urea only contains the same gas in the ratio of 2 to 8, or one-quarter of the whole. I myself have for a long time adhered to the doctrine still accepted by continental and by most, if not all, American physicians, which maintains that the formation of uric acid is the result of a lower degree of oxydation of the elements that compose it than that of the same elements constituting urea. I have renounced it, however, from conviction, but am prepared to acknowledge my error when proved to be wrong.

(To be continued.)

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

Cases under the care of Mr. CROLY.

Case 1.—RANULA OF LARGE SIZE—OPERATION—SUCCESSFUL RESULT.

F. M., aged 63 years, residing in the county of Louth, was admitted into the surgical wards of the City of Dublin Hospital, suffering from a tumour under his tongue.

History.—The growth commenced about thirteen months previously to his admission, and increased gradually in size; it caused the patient much annoyance latterly by interfering with speech and deglutition; the saliva was constantly flowing from his mouth; on one occasion he experienced a most distressing sense of suffocation. On examination, a large Ranula was observed occupying the entire right side of the cavity of the mouth; the tongue was displaced backwards, and to the left side; when the patient was told to put out his tongue, the tip appeared behind the tumour. The saliva poured from his mouth, and his speech was so inarticulate that it was difficult to understand what he said.

The tumour was hard at the base, and had a fluctuating feel on the anterior surface. The patient said he lost flesh, which he attributed to the waste of saliva.

Operation.—The patient having been seated in a chair, Mr. Croly raised the anterior wall of the cyst with a tenaculum, and cut a circular piece out, the size of a shilling, by means of a sharp-pointed scissors. The cyst contained, near the surface, the characteristic glairy fluid, like white of egg, but the sac was chiefly filled with solid matter, which was removed with the handle of the scalpel. There was very little hæmorrhage; the cavity was filled with lint; the interior of the cyst was subsequently touched freely with nitrate of silver, and the part healed by granulation.

The patient was discharged from hospital perfectly cured.

Mr. Croly gave a brief clinical lecture on this disease. He mentioned the various causes assigned for this affection, amongst which he alluded to obstruction of the salivary duct and the development of a special cyst. He also enumerated different modes of treatment—the most successful being that adopted in this case, viz.:—the removal of a portion of the cyst, emptying out the contents, and finally touching with nitrate of silver; the seton or drainage-tube being only suitable for cases of Ranula with fluid contents.

Case 2.—HARE-LIP—OPERATION, LEAVING SCARCELY A TRACE OF DEFORMITY.

M. S., aged two months, was admitted into hospital under Mr. Croly's care, for the purpose of being operated on for hare-lip. The fissure was at the left side, and did not extend into the nostril. There was no cleft in the palate.

The operation was performed in the following manner:—The child having been secured in a sheet, was held steadily in the lap of an assistant. The lip was first freely detached from the inside by a small scalpel, and the edges were cut with a curved hare-lip scissors. A fine hare-lip pin was next introduced near the red margin, and at a distance of at least a quarter of an inch from the edge of the fissure. It was passed down as far as the mucous membrane, and through the opposite side in a similar manner.

A twisted silk suture was applied with moderate tightness, and a second pin, with twisted suture, was introduced above. The edges came into perfect apposition, and strips of adhesive plaster were applied from one cheek to the other, to keep off all strain from the sutures.

The child was not allowed to suck for some hours.

The pins were removed in seventy-two hours; the lip was found to have united most accurately, leaving scarcely a trace of deformity.

Mr. Croly observed on the advantages of early operation for hare-lip, and dwelt specially upon the importance of detaching the lip from the inside before paring the edges. He recommended the use of the curved scissors, and showed some drawings of cases operated upon by him with that instrument, which were most satisfactory.

The manner of introducing the pins, and the application of the twisted suture, was also dwelt upon.

RICHMOND SURGICAL HOSPITAL.

CASES UNDER THE CARE OF MR. WILLIAM STOKES.

(Reported by Mr. JAMES A. ROSS.)

STRANGULATED INGUINO-SCROTAL HERNIA—DURATION OF STRANGULATION FIVE DAYS—HERNIOTOMY—SAC OPENED—UNFAVOURABLE TERMINATION OF THE CASE.

IT has been truly remarked that almost every case of strangulated hernia is characterized by some unusual and peculiar feature. The following case, which was recently under observation in Mr. Stokes' wards, in the Richmond Hospital, and which presented some peculiarities which rendered its exact diagnosis a matter of considerable difficulty, is strikingly illustrative of the truth of this observation.

John Wade, aged 21, was admitted into the Richmond Hospital on the 29th of June, having been recommended to Mr. Stokes by Mr. Charles Gray. The patient stated that about twelve months ago, he got a fall from a horse, in consequence of which the right testicle was injured, and became very much inflamed and swelled. This, after a time, subsided, and then, shortly after this, the patient observed a small tumour in the scrotum, which he never could reduce fully, but, without doubt, to a certain extent. On the night of the 24th ult., without any assignable cause, the tumour became somewhat larger, and this was accompanied by an attack of vomiting. The following day, the vomiting having subsided, he was able to go to his employment, but on the evening of that day—the 25th—the tumour became larger and much more tense, and vomiting again set in, and the patient continued in this condition, vomiting at intervals, and with his bowels confined until the 29th—the day of his admission into hospital. Owing to the strangely contradictory statements the patient made, whose intellect, owing probably to his great suffering, was in a perfectly distracted condition, it was a matter of extreme difficulty to elicit even these few particulars of his case.

On the patient's admission into hospital, a small tumour about the size of a hen's egg, was found in the scrotum. In the situation of the cord, a little external to the external abdominal ring, the tenderness and pain were extreme. This was not the case in the scrotal tumour, which was free from tension, pain, and impulse on coughing. The tumour was somewhat pyriform in shape, and the scrotal portion of it felt not unlike a varicocele; this, as was subsequently ascertained, was caused by this portion of the tumour being made up of omentum. The epididymis could be distinctly felt, and the testicle easily isolated. On percussing the tumour, the sounds were absolutely dull, and there was no translucency. Since Thursday, the 25th ult., five days previous to his admission, the bowels had not acted. His face was pale and anxious-looking, and he was perspiring profusely. The pulse was very weak, quick, and compressible, being 120; vomiting continued during the day. In the evening the bowel—probably the portion only below the strangulation—was cleared by an enema. There was considerable fulness, pain, and tympany over the abdomen.

Taking into consideration the want of tension in the tumour, the absence of impulse on coughing, the fulness, pain, and tension being localized solely in the cord, the question to determine was whether the case was one of strangulated inguino-scrotal hernia, or an omental hernia combined with acute inflammation in the cord. This condition, though very rare, has occasionally misled the most accurate observers. The practice Mr. Stokes determined on was, in the first instance, to observe the effects of local depletion and stuping, &c., for a short time, and that then, should the symptoms of strangulation persist, to cut down in the situation of the external ring, and return the tumour should it prove hernial. Several leeches were applied, followed by hot stuping, and at 9 P.M., Mr. Stokes finding that the symptoms had not ameliorated, and that the patient was obviously becoming weaker, determined on performing the ordinary operation for strangulated inguinal hernia.

On dividing, carefully, the structures in front of the tumour, the latter was found to be hernial, the greater proportion of which was found to consist of omentum, not by any means gangrenous, but in an extreme state of congestion. At the upper portion of the tumour, a small knuckle of intestine was found, and of a dark chocolate colour. The protruded intestine was completely surrounded by omentum. There was no difficulty, after dividing the stricture, in returning the intestine into the abdomen, but the reduction of the omental portion of the tumour was, owing to extensive adhesions, attended with very great difficulty. The hernial tumour, however, was, after some time, completely reduced. After the operation the patient got a powerful anodyne draught, containing opium, Hoffmann's anodyne, and hydrocyanic acid. During the night, he slept for some hours; the pulse became stronger and fuller, but still compressible; his face lost its anxious look, and its colour improved.

June 30th.—The vomiting continues; there is scarcely so much pain over the abdomen; bowels not moved; pulse 120, stronger and better; he complains of much thirst, and perspires freely. He was then ordered one grain of calomel every hour, leeches to the abdomen, mercurial inunction in the axilla and over the abdomen, and, internally, opium and iced brandy, with dilute hydrocyanic acid. As the day advanced he became very restless; the vomiting continued; the forehead was covered with large drops of perspiration, and the feet and hands grew clammy and cold; the great thirst remained throughout the day quite unrelieved. The pulse rose until, at midnight, it was over 150, and at two o'clock A.M., twenty-nine hours after the operation, the patient sank.

The autopsy revealed a state of things which would render recovery under such circumstances quite hopeless.

The intestines were very vascular from the extensive and violent peritoneal inflammation, and lymph was extensively thrown out all over them, in fact, glueing them all firmly together. They were also greatly inflated above the seat of the stricture. The omentum was carried down in a strong band, and had contracted adhesions with the sac in the scrotum. The portion of the small intestine about the constriction, which was near the ilio-cœcal valve, was approaching a state of gangrene, and the portion of intestine below this was contracted.

In some clinical remarks to the class on this and other cases of strangulated hernia, which have recently been under observation in the Richmond Hospital, Mr. Stokes mentioned the leading peculiarities and features of each. He also drew attention to the general principles of treatment for all such cases, both before and after operation. Special mention was made as to the use of opium in such cases, and it was pointed out how its inconsiderate use before operation may, by causing the subsidence of vomiting, one of the most important and characteristic symptoms of strangulation, mislead the incautious surgeon, who in consequence of the apparent amelioration in the patient's symptoms, may either defer the operation to too late a period, or, labouring under the erroneous belief that strangulation no longer existed, abandon it altogether. The great advantages of opium after operation were then dwelt on, and Mr. Stokes mentioned that the chief reason for its administration after operation is analogous to that for which atropine is principally given in cases of acute Iritis; in both cases the great object of the surgeon being to bring the muscular structures in the one case of the intestine, and in the other of the Iris, into a state of quiescence or repose, these objects being attained respectively by opium and by atropine. In the case of Iritis, frequent use of atropine is much more important in bringing about absolute rest of its muscular fibres, than for diminishing the chances of posterior synechiæ by keeping the iris dilated, or, as it undoubtedly does, acting as a local narcotic.

DR. STEEVENS' HOSPITAL.

CASES UNDER THE CARE OF MR. COLLES.

RETENTION OF URINE, WITH PUNCTURE OF BLADDER.

DANIEL CONOLLY, æt. 21, was admitted into hospital on Sunday, June 21, under the following circumstances:—He had, on previous occasions contracted gonorrhœa, and was then labouring under that disease. The night before he had indulged to a large amount in drink, principally porter and whisky, and found himself in the morning unable to pass urine. On examination, the bladder was enormously distended, its outline distinct on the abdomen. He was evidently suffering severe pain, although partially stupid from intoxication, and making violent straining efforts to pass water. All attempts to pass a catheter were unavailing, the extreme congestion of the urethra being denoted by the occurrence of hæmorrhage on the gentlest trial of the instrument. The warm bath, and all other general methods that could be devised for affording relief, were successively adopted, but without success. The symptoms of distension being very urgent, it was at length determined to evacuate the bladder by puncture, which was done through the rectum. Nearly 70 ozs. of urine, by measure, were drawn away. The canula was retained in the bladder by means of tapes.

22nd.—The urine has passed freely through the opening in the rectum; the canula has slipped out. A catheter of the railroad kind, used by the late Dr. Hutton, was passed into the bladder through the urethra. Over the fine catgut director an instrument was introduced without much difficulty, and retained in the bladder.

23rd.—The instrument was withdrawn; the urine has ceased to pass through the artificial opening.

29th.—The man has left hospital to-day, passing water freely through the urethra. There is some gonorrhœal discharge, for the treatment of which he has been directed to come to the hospital dispensary.

This case seems to show very definitely that the class of strictures, usually known by the term spasmodic, are more dependent on a congested state of the mucous lining of the urethra, which condition may be sufficient as well to cause complete retention, as to create a formidable difficulty in ordinary catheterism. The small amount of inconvenience resulting from the puncture, and rapid recovery, are worthy of notice.

LARGE MALIGNANT TUMOUR OF BREAST: REMOVAL: RECOVERY.

R. Smith, æt. 49, was admitted into hospital in March 1868. He had the aspect of rude health, having a florid complexion and cheerful expression of countenance, and was remarkably large, weighing 322 lbs. He was suffering from a large tumour in his right breast, which had been growing about fourteen months; it had at that time attained the dimensions of a child's head, and had ulcerated in one place, from which he had some severe attacks of hæmorrhage. After remaining in hospital about a week, the tumour was removed by an oval incision—it weighed three and a-half lbs., and on microscopic examination was found to be distinctly cancerous in its nature. The wound healed rapidly, and the man left hospital three weeks after the operation. This case has some interest in showing that the possession of a robust frame and plethoric habit of body confers no immunity from the development of malignant disease. Many instances have recently occurred in this institution, where cancer has made its appearance in individuals apparently of the strongest and most healthy constitution.

◆

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

PHARMACY.

THE following is the report of the Pharmacy Bill Committee, which we promised, owing to its importance to the profession at large, to give *in extenso*:—

The Committee appointed to consider and report on the Bill for the regulation of pharmacy now before Parliament, beg to submit the following report to the General Medical Council; and they desire to state that, in considering the matter, they have had the advantage of the presence of Mr. Sandford, President, and of Mr. Bremridge, Secretary of the Pharmaceutical Society.

The course adopted was, in the first instance, to read the recommendations, in order, of the Committee of the General Medical Council on the pharmacy question in 1865, and to ask the President and the Secretary of the Pharmaceutical Society for information as to the reasons of the promoters of the Bill for not adopting the suggestions of that Committee. Mr. Sandford and Mr. Bremridge most kindly and most frankly met all the questions. The following are the questions and replies, divided under the two heads, "Pharmacy," and "Sale of Poisons."

PHARMACY.

Suggestion No. 1.—Why was this suggestion, proposing to extend the Bill to Ireland not adopted?

Reply.—1st. That the Pharmacy Bill of 1852 did not extend to Ireland.

2nd. That the promoters were informed that the dispensing chemists of Ireland were a superior class of men to those in England.

3rd. That the promoters do not now object to the extension of the provisions of the Bill to Ireland.

Suggestion No. 2.—Why was it not rendered imperative on all chemists and druggists to follow the formularies of the British Pharmacopœia in compounding prescriptions?

Reply.—It was considered that such compulsion was not within their jurisdiction, but belonged wholly to higher authorities. The promoters do not object to the insertion of such provision.

Suggestion No. 3.—Why are persons admitted on what appear to be too easy terms, and why are the privileges proposed in 1865 to be given only to those then in business, now extended by the present Bill to a wider class of unqualified persons?

Reply.—That such extension was given by Parliament in protection of vested interests; that a committee of the House of Commons in 1865 recommended such extension, and that without such extension the Bill would have no chance of passing through Parliament.

Suggestion No. 4.—Why is some provision not inserted to prohibit dispensing chemists from practising any branch of Medicine or Surgery?

Reply.—1st. That the power to prevent unqualified persons from practising Medicine or Surgery rested, in their opinion, with a higher authority.

2nd. That they object as strongly as any others to dispensing chemists practising Medicine or Surgery, and that Sect. VIII. of the Pharmacy Act of 1852, which remains in force by this Bill, strictly excludes any examination in Medicine, Surgery, and Midwifery from the examinations.

SALE OF POISONS.

Suggestion No. 1.—Why are not the provisions of the Arsenic Act extended to the sale of all the more fatal poisons?

Reply.—That the provisions of the Arsenic Act remain a dead letter.

Suggestion No. 2.—What restrictions as to sale of poisons are to be imposed upon registered chemists?

Reply.—There was no restriction in the original draft, but Clause No. 1, as amended in the House of Lords, provides that all chemists shall "conform to such regulations as to keeping and selling of such poisons as may be prescribed by the Pharmaceutical Society, with the consent of the Privy Council."

The promoters of the Bill consider this restriction quite sufficient.

Suggestion No. 3.—Why does not the list of poisons in Schedule (A) include opium?

Reply.—Opium was included in the first draft of the Bill, but the promoters of the Bill received such strong representations from chemists residing principally in Cambridgeshire, Lincolnshire, and Norfolk, against interfering with their business—opium, as they stated, being one of their chief articles of trade—that the promoters felt compelled to strike opium out of Schedule A; but that clause 2 of the Bill provides for the addition, from time to time, of any article deemed a poison to Schedule (A), with the consent of the Privy Council, and that, at any time, it and any other poisons might be so inserted.

Your Committee now beg to report their own conclusions, and they would here recommend the introduction of the single word "pharmacist," for the several terms now used, "chemist and druggist," "compounding chemist," "pharmaceutical chemist," &c.

PHARMACY.

Your Committee desire, in the first place, to correct a mistake in the information conveyed to the promoters of the Bill —viz.: "That the dispensing chemists of Ireland are a superior class of men to those in England." The fact is, that there are no such persons in Ireland as compounding chemists, while there are more than 6000 compounding chemists in England and Wales. The only persons permitted to compound medicines in Ireland are licentiates of the Apothecaries' Hall of Ireland, any other person opening a shop for compounding medicines in Ireland being liable to a fine of £20 for every offence of compounding a prescription, at the prosecution of the Apothecaries' Hall of Ireland, and to obtain such licence it is required by the Apothecaries' Hall of Ireland that the candidate should have gone through a four years' course of study of anatomy, surgery, medicine, and midwifery.

Your Committee are of opinion that some provision should be introduced into the Bill by which pharmacists, duly examined according to the provisions of the Pharmacy Act of 1852, and registered under the proposed Act, shall be permitted to open shop in like manner in Ireland, as in England, without being liable to prosecution or infliction of penalty; and that if there be any obstacle in the Apothecaries' Act of Ireland to prevent the licensing by the Apothecaries' Hall of Ireland of pharmacists in Ireland, that that obstacle should be removed, giving reciprocity of practising pharmacy throughout the United Kingdom.

In reference to the introduction of a clause rendering it compulsory on pharmacists to follow the formulary of the British Pharmacopœia, the Committee observe that the obligation to compound according to the formulary of the British Pharmacopœia is provided for to some extent by sections 2 and 3 of Act 25 and 26 Vict. c. xci., which are as follows:—

Sect. II.—"The exclusive right of publishing, printing, and selling the said Pharmacopœia shall rest in the said general Council, subject to this proviso: that it shall be lawful for the Commissioners of the Treasury from time to time to fix the price at which copies of the said work are to be sold to the public."

Sect. III.—"The British Pharmacopœia, when published, shall for all purposes be deemed to be substituted throughout Great Britain and Ireland for the several above-mentioned Pharmacopœias, and any Act of Parliament, order in Council, or custom relating to any such last-mentioned Pharmacopœias shall be deemed, after the publication of the British Pharmacopœia, to refer to such Pharmacopœia."

Your Committee regret that this Act of Parliament, or the above sections, were not printed in the last edition of the Pharmacopœia, as they were in the first, and suggest to the Council the propriety of giving them publicity.

Your Committee are, however, of opinion that the above sections are not sufficient to enforce the desired object, and recommend that a provision should be introduced into the Bill to render it imperative on all registered pharmacists to dispense medicine in strict accordance with the British Pharmacopœia, unless, when otherwise specially directed in written prescriptions.

Your Committee beg to call particular attention to the provisions of this Bill, which would register indiscriminately every person who may be at the present time engaged even partially in the business of chemist and druggist. The proposal in this Bill goes farther than the corresponding proposal in the Bill of 1865, inasmuch as it would qualify for registration every assistant and every apprentice of two years' standing. To such extensions your Committee strongly object.

In a measure which constitutes a registered body, to which would be committed the power and responsibility of dispensing medicines which may be poisonous, or injurious, or worthless, if not properly prepared and from pure materials, some better plea for indiscriminate registration should be adduced than the protection of vested interests. The health and safety of the community are surely of more consideration than the vested interests of traders. Your Committee therefore recommend that the legalised right to dispense medicine should be confined to members of the Pharmaceutical Society, and to such other existing chemists and druggists as the Council of that Society may recommend for the privilege of registration.

On the question of inserting a stringent clause in the Pharmacy Bill to prevent pharmacists from practising any branch of Medicine or Surgery, your Committee observe that they would be liable, in common with all other unqualified persons, to the penalties provided in the Medical Act of 1858, but your Committee are of opinion that such provision is not sufficient, and that a provision of a similar kind to that recommended by the Committee of 1865 should be added to Clause 16 of the present Bill, after the words "Medical Practitioner," viz.:—"or entitle any person registered under this Act to practise Medicine or Surgery, or any branch of Medicine or Surgery."

SALE OF POISONS.

Your Committee, as already stated, are informed that the provisions of the Arsenic Act have become a dead letter; and if such be the case, they would not recommend that the provisions of the said Act should be embodied in this Bill.

Your Committee are of opinion that Clause No. 1 of the present Bill would sufficiently provide for the regulation of the sale of poisons, if the same power were extended to the General Medical Council as to the Pharmaceutical Society, viz.:—to represent to the Privy Council what in their opinion should be inserted in Schedule A as poisons, and, from time to time, to make such other representations to the Privy Council for the protection of the public as may seem advisable.

With regard to the omission of opium from the list, your Committee are of opinion that opium should be inserted either at once, or under the provisions of Clause 1; and that the reasons which have been put before this Committee, viz.:—that regulations as to the sale of opium would interfere with the trade profits of druggists in certain parts of England—constitute, in the opinion of your Committee, the strongest grounds for inserting opium in the list of poisons.

With regard to the sale of opium and other poisons in Ireland, there is already in force in Ireland an Act, 31 Geo. III., cap. 34, applying to the sale of arsenic, &c.; and it may be advisable, in the next session of Parliament, to consider the expediency of extending the provisions of that Act, or of the present Bill, to that part of the United Kingdom.

Dr. RUMSEY said he regretted the Committee had only had the opportunity of conferring with the representatives of one of the bodies which were promoting this Bill—namely, the Pharmaceutical Society; the other large body—the chemists and druggists of the country—they had not yet been able to communicate with. He also regretted that it did not appear practicable to adopt the Pharmaceutical Society under the Act of 1852 as a basis of legislation. It would then have been necessary merely to prohibit the use of the title of pharmaceutist by those who were not on the register, dealing with them just in the same way as unregistered Practitioners of Medicine were dealt with by the Medical Registrar—not prohibiting such as were now in business to continue their occupation, but not allowing them to be on the Register, which would give them a sort of legally established position in the country. The number of chemists in the country was very much larger than it was stated to be by the Pharmaceutical Society, who put the number at between 6000 and 7000, whereas, taking the census of 1861, there were found to be not less than 16,000 males entered as belonging to the occupation. No doubt many of them would be assistants, but still the difference between 6000 and 16,000 was rather astonishing. The Committee were unanimous in desiring not to interfere, further than was necessary for the public health and safety, with chemists and druggists now in business. The Apothecaries' Act of 1815 had been quoted on behalf of existing interests, but that did not apply to the present proposal, because it did not create a registration of members, but merely protected existing members from any interference.

Mr. COOPER said there was a register kept at the Apothecaries' Hall for the purpose.

Dr. RUMSEY was sorry the great principle of supervision had been omitted in the present report. Perhaps it was prudently done, but he was bound to say it was a principle which the Council had already laid down in a report adopted by them. Add to that the fact that England was the only country in the civilised world where pharmaceutical chemists were not subject to control, and he thought he sufficiently justified himself in calling the attention of the Council to the matter. With regard to Mr. Sandford's statement that the provisions of the Arsenic Act had become a dead letter, after having the advantage of hearing a statement of Mr. Simon upon the subject, he could not admit the truth of the assertion. He believed that those provisions had exercised a most salutary effect in curtailing the unlimited sale of so frightful a poison as arsenic, and he would have liked to see in the report a recommendation for applying similar safeguards to the sale of other poisons. He was sorry to say that the Pharmacy Bill now under discussion did not give that power. It gave power solely to the Pharmaceutical Society, *with the consent of the Privy Council*, thus leaving the initiative with the Pharmaceutical Society. With regard to the sale of opium, the reply received from the Pharmaceutical Society was most curious and instructive—namely, it "was included in the first draft of the Bill, but the promoters of the Bill received such strong representations from chemists residing principally in Cambridgeshire, Lincolnshire, and Norfolk against interfering with their business—opium, as they stated, being one of their chief articles of trade—that the promoters felt compelled to strike opium out of Schedule A." It was a very remarkable thing that those three counties the Medical Officers of the Privy Council had shown to be distinguished for the highest rate of infant mortality in the kingdom, and they attributed this mortality and the degeneration of race that was going on in those counties to the enormous consumption of opium—yet, with that frightful fact before the community, the promoters of the Bill struck out the word opium in deference to the traders in those counties. He now moved that the report be adopted by the Council, following upon which some resolutions would be moved by Sir D. Corrigan on the subject.

Dr. QUAIN thought the report should be discussed paragraph by paragraph, because to some parts of it he felt bound to offer considerable opposition. For example, it was most desirable that the Act should extend to Ireland, but, on the other hand, that all chemists should adopt the British Pharmacopœia was most inconvenient. No one had greater desire to extend the Pharmacopœia than he had, but to adopt it indiscriminately and by force of law in that way would lead to very dangerous results. For example, many were in the habit of having old prescriptions made up; a chemist in such case might be guided by his reason and judgment; but under the proposed clause, as far as he understood it, a chemist had no alternative under the law but to use the British Pharmacopœia. He had consulted some of the principal chemists and druggists upon the subject, and they said it would be a most dangerous thing to insist upon the indiscriminate and compulsory use of it.

Sir D. J. CORRIGAN, in introducing the first resolution founded upon the report—"That the term pharmacist be introduced into the wording of the Act as synonymous with the terms compounding chemist, pharmaceutic chemist, chemist or druggist"—said the word "pharmacist" had been chosen by the Committee as more in accordance with the usage on the Continent, and also as a term which it was thought would in time supersede the variety of terms at present in use.

The resolution was seconded by Dr. STORRAR, and unanimously adopted.

Sir DOMINIC CORRIGAN, in moving the second resolution—"That, from and after the passing of this Act, 'pharmacists,' or 'dispensing chemists,' or 'druggists,' duly qualified to open shops or establishments in England for the compounding of medicines, shall in like manner be duly qualified to open like shops or establishments in Ireland, and shall not be liable to penalty or fine for so doing, and that in like manner persons licensed in pharmacy, and registered by the Apothecaries' Hall of Ireland, shall not be liable to penalty or fine for so doing in Great Britain"—said that, whereas the Bill provided certain poisons should not be sold by such and such persons unless they conformed to such regulations as to the sale of them as might be prescribed by the Pharmaceutical Society with the consent of the Privy Council, the Committee proposed to introduce the words "or by the General Medical Council," thus giving them power to initiate any steps they might think necessary.

Dr. ANDREW WOOD was pleased that a new class of dispensing chemists (who would not assume the power of prescribing) would, by this resolution, be introduced into Ireland.

In moving the third resolution—"That in clause 1 of the Pharmacy Bill, after the words 'may be prescribed' should be inserted the words 'by the General Medical Council or,' and that in clause 2, line 3, similar words should be inserted after the word 'and,' and again after the word 'thereupon' in line 7"—

Sir D. J. CORRIGAN said the object was to give power to the General Medical Council as well as the Pharmaceutical Society to suggest to the Privy Council such questions as this—that certain dangerous drugs should be put into Schedule A containing poisons dangerous to human life and health.

Mr. HARGRAVE seconded the resolution, and after discussion the resolution was put to the vote and negatived, as was also an amendment by Dr. RUMSEY that the words "the Pharmaceutical Society with the consent of" be omitted from the Bill—thus leaving the initiative with the Privy Council.

THE SALE OF OPIUM.

Sir D. J. CORRIGAN, upon this subject, moved "That 'opium' should be inserted in Schedule A." This was unanimously adopted.

DRUGGISTS' ASSISTANTS AND APPRENTICES.

The following resolution, moved by Sir D. J. CORRIGAN, and seconded by Dr. ANDREW WOOD, also received the assent of the Council: "That clauses 3 and 4 be so amended as to limit the registration of 'pharmacists' or chemists and druggists to members of the Pharmaceutical Society, and to such other existing chemists and druggists as the Council of that Society may recommend as fit to be placed on the registry."

THE NEW PHARMACOPŒIA.

Sir D. J. CORRIGAN moved "That all pharmacists shall be required to compound medicines according to the formularies of the British Pharmacopœia, unless otherwise specially directed in the written prescriptions."

Dr. QUAIN objected as before to such a clause, in consequence of the hardship and inconvenience which he was convinced from practical knowledge it would impose upon pharmaceutical chemists. It was a well-known fact that certain medical men did not use the British Pharmacopœia, and at the same time did not indicate that fact upon their prescriptions. Chemists at present knew, from the quarter whence the prescription came, that it was intended to be made up under the London Pharmacopœia. But unless this was distinctly stated, under the proposed clause, they would be compelled by law to dispense under the British Pharmacopœia and no other; and the responsibility of any mishap would be thrown back upon the medical man.

This resolution was also carried, and the next and last resolution on the subject was agreed to—

THE PRACTICE OF MEDICINE BY PHARMACISTS.

"That there shall be a clause introduced, providing that registration under this Act shall not entitle any person so registered to practise medicine or surgery, or any branch of Medicine or Surgery."

It was then moved, "That a deputation consisting of the President, Sir Dominic Corrigan, Dr. Rumsey, Dr. Leet, and Dr. Alexander Wood, be requested to place, without delay, before the Home Secretary, the resolutions of the General Medical Council in reference to a report of the Pharmacy Bill Committee this day considered by the General Council, placing in his hands both the report of Committee, and the resolutions adopted by the Council."

The deputation, as proposed, thereupon left the Council for the purpose stated, and returned at a subsequent period of the meeting, Sir Dominic Corrigan, in the absence of Dr. Rumsey, Chairman of the Committee on Pharmacy, reporting to the Council that the deputation had had an interview with Sir James Fergusson, Bart., Under-Secretary of State for the Home Department, and had handed to him the resolution of the General Medical Council previously agreed to, and that Sir James Fergusson had promised to give the resolutions and report of the Committee his best attention in the progress of the Bill through the House.

The Council having expressed themselves satisfied with the result of the deputation, the subject dropped.

Literature.

PROFESSOR MOSLER ON THE TREATMENT OF TYPHUS FEVER.[1]

A WORK on such an important subject as the treatment of typhus fever undoubtedly is, written by a teacher of clinical medicine at one of the largest schools in Germany, has a just claim on our immediate attention. On Professor Mosler's ability to treat his subject in such a manner as to make it profitable both to science and the practitioner, we need not dwell. But it may just be mentioned, that the author's researches on entozoæ and mykology have placed him in the foremost position amongst the authors of this department.

The work is divided in six parts, treating on the following subjects:—

1. Prophylactic measures, by means of which an epidemic in the district of Franzburg has been kept within its original limits, and soon quenched.
2. Statistics of cases of typhus fever treated in the Hospital of Stralsund.
3. Experiments on the contagiousness of typhus fever, and on the prophylactic measures derived thereform.
4. Description of barracks of the Greifswald University Hospital, and the results obtained therein, during winter, in typhus and other diseases.
5. Statistics of cases of typhus fever, treated in the University Hospital of Greifswald, during 1866-1867.
6. General remarks.

To treat on all parts separately and in such a manner as they deserve, would imply a reproduction of nearly the whole book. That being impossible, we must confine ourselves to two parts which we consider of the utmost importance, and leave with the reader the perusal of the book itself, if they feel more deeply interested in the subject.

The first of the two points concerns the experiments in respect to the contagiousness of typhus fever.

Professor Mosler maintains, acknowledging the correctness of Pasteur's researches, according to which fermentation and putrefaction are induced and conducted by vegetable or animal organisms of a lower order, that by influence of the same minute beings, animal and human substances may become infectious. This applied to typhus fever, our whole care must tend towards the prevention of the secretions and excretions of the patients, undergoing decomposition, by means of the products of which contagiousness is principally engendered. The most simple and the most convenient way of arriving at the desired end, is the immediate removal of the secretions and excretions from the wards, and the cleanliness of the patients, by putting them often into a bath. The whole procedure, as adopted in the treatment of typhus, by means of water, according to hydro-therapeutical principles, frequent change of linen, keeping clean all parts of the patient's body, prevents the development of a nest of contagion immediately around the patient.

Professor Mosler has experimentally shown the part played by lower organisms in decomposing secretions and excretions from patients labouring under typhus fever, to be really great, and that their origin and multiplication must by all means be prevented.

1st Experiment.—On 8th April, 65 C. cent. of blood from a patient suffering from typhus fever, whose morning temperature on about the sixth day of his illness was 40·3 C. in the axilla, were defibrinised and injected into the right jugular vein of a dog, after having emitted from the same vessel a quantity of blood, equal to that injected. Immediately after transfusion the animal became infirm on its legs, but gradually recovered, exhibiting only during the day of injection a higher temperature, thirst, and passed urine somewhat mixed with blood. On the next day, the dog was perfectly well, and continued so.

2nd Experiment.—A patient, whose temperature on the seventh day of illness was 40·5 C. at five in the afternoon, whose pulse was 130 in a minute, who exhibited numerous petechiæ and all other symptoms of typhus fever, was bled, and about 90 C. cent. of blood was drawn, at once defibrinised, and still warm, about 40 C. cent. of it injected into the left jugular vein of a dog; no abnormal appearances could be observed, and the animal continued in perfect health.

3rd Experiment.—On the 8th of April, a quantity of blood was taken from the right ventricle of a patient, who died from typhus fever. It remained twenty-four hours in the vessel, and contained after that time a very large number of Bactriæ. It was filtered, raised to a temperature of 31 R. and 60 C. cent., injected into the right jugular vein of a healthy dog. Immediately after injection, no perceptible alteration of the animal, but a few hours afterwards vomiting, intense fever, profuse diarrhœa set in, the animal collapsed rapidly and died after twenty-two hours. On post-mortem examination, the sinuses of the brain were found filled with blood, the same in the envelopements of the brain, the latter exhibiting some small extravasations. No catarrh in the lungs; on the surface of the anterior rim of the left lung, a few small extravasations were visible. A small hemorrhagic infaret, which, however, could not be shown dependent on embolism. Heart normal, liver normal, spleen voluminous, containing much blood, but soft. Kidneys congested. Bladder filled with fluid of a reddish yellow colour, containing albumen. Bowels remarkably altered, being thoroughly filled with a dark bloody mass; mucous membrane swelled, hyperæmic containing extravasations, even the stomach was filled with the same dark bloody mass as the bowels.

Small as the number of experiments is, and negative as are the results of the two first experiments, yet they sufficiently show the blood of a typhus-patient, when immediately transfused into an animal, does not under all circumstances produce typhus, but only acts as blood of any other patient suffering from some kind of fever, and experiments recently made by Frese have even shown that larger quantities of healthy blood produce fever symptoms, if a venesection has preceded infusion, from which fact Frese considers increased reception of products from physiological decay into the blood, as the cause of raise of temperature after bleeding, and after transfusions following such bleedings.

From the positive results of the third experiment, Prof. Mosler concludes, that the blood, as well as the secretions and excretions from typhus-patients, assume deleterious properties, when some time under the influence of the atmosphere, and when decomposed by lower vegetable or animal organisms. In fresh typhus-blood Bactriæ could not be discovered.

Some feeding experiments made with dejections from patients suffering from typhoid fever, are of great interest, and may briefly be mentioned.

4th Experiment.—On 31st October, 200 C.C. of typhus-stool from a patient suffering from typhoid fever, whose evening temperature in the second week of illness was 40·2 C., morning temperature 39·6 C., were given by means of a funnel, to a strong, healthy dog. No vomiting after infiltration. The stool has been evacuated during the night from the 30th to 31st October, and infiltrated on the 31st October, at 11 o'clock A.M. The microscope showed the usual elements of typhus-stool, but there were already numbers of vibriones. Reaction intense alkaline.

On the first of November, temperature in the rectum of the dog 39 C. On the next day the animal was perfectly healthy; no diarrhœa.

---

[1] Erfahrungen über die Behandlung des Typhus exanthematius mit Berücksichtigung dabei erfor derlicher prophylakticher Maassregeln, für Aerzte und Sanitätsbeamte mitgetheilt von Dr. Fr. Mosler, ordentlichem Professor der Medicin, Director der Medicinischen Kilinck an der Universität Greifswald, Mit. 1, Tafel, Greifswald, Akademische Buchhandlung. 1868.

On the third of November, 25 C.C. of typhus-stool five days old, have been given to the same dog. The stool contained large masses of vibriones, reaction intensely alkaline. No symptoms perceptible during the first few days, but on the 9th November the animal declined taking food; had rigors, shiverings, was emaciated, and died on the 14th November.

On the post-mortem examination, ulcers of the intestines and other products were seen as are usually met with in cases of typhoid fever.

5th Experiment.—On the 28th November, 600 C.C. of fresh typhoid-stool was given to a dog, and all precaution taken to prevent the fluid being returned by vomiting.

On the 29th the animal was uneasy; took but little food; was very fœtid, but recovered the next day. Temperature measured in the rectum was not raised.

	MORNING TEMP.	EVENING TEMP.
26th November	38·8 C.	39·1 C.
27th „	38·6 C.	39·1 C.
28th „	38·9 C.	39·2 C.
29th „	38·6 C.	39·1 C.
30th „	38·6 C.	39·1 C.

No symptom of disease was afterwards observed in the dog. While repeating the experiment on another dog with stool which had been standing for five days, and containing large masses of vibriones, the whole quantity was returned by vomiting. Nevertheless, the dog fell ill, but ultimately recovered, which Prof. Mosler takes as evidence that the smallest quantity of stool, when putrefied, may give rise to disease.

(To be continued.)

WEDNESDAY, JULY 22, 1868.

THE MEDICAL DEPARTMENT OF THE ABYSSINIAN EXPEDITION.

MEDICAL Officers in the army complain, with good reason, that their labours with our troops in all climates, and under every circumstance of military service, neither obtain for them the rewards and distinctions that are bestowed on military men, nor those that the more successful of their professional brethren in civil life receive. They justly consider that they are thus in a most unfavourable position in these respects; nor can exception be taken to the point of view from which they consider their position.

It is not enough to assert that in any improvements in their social status, pay and prospects on retirement have of late years been effected, nor to remind them that only within the present century has the custom been established of any notice being taken in "orders" by commanders of their services at all. These facts are not denied, although when contrasted with the improvements effected in the status of the medical practitioner in civil life, and in the condition of the army military officer, they hesitate to believe that, as compared to either, they have not been left behind. Knighthood and baronetcies have been conferred upon medical men practising in civil life; similar and far greater rewards upon generals employed in the different wars in which our troops have, during the last fourteen years, taken part. But as to the medical officer! let us look at the Army List, and we there find there is not among the names of those now on full-pay any distinctive honour beyond the Companionship of the Bath.

The omission of the Medical Officers attached to the army in Abyssinia in the vote of thanks to all other departments connected with that force, is an illustration in point, and has, in fact, given rise to these remarks. Under ordinary circumstances, to omit all mention of the officer at the head of an administration, implies censure of that officer, and of the department under him. Dr. CURRIE, fortunately for himself, had already established his reputation as an able administrator and first-rate medical officer, and had this not been the case the accounts given by correspondents with the force, not to mention the recognition of his services in the despatches of Sir ROBERT NAPIER, amply testify to the importance of the services that, on this occasion, have been rendered by him and the medical officers employed under his orders.

It is clear, then, that the non-recognition of those services, rests not with the General in command. No man knows better than Sir ROBERT NAPIER the value of an efficient medical department, and no man is more ready than he to give to each the credit to which he is justly entitled, whether he be military, medical, commissariat, or other "departmental" officer. How comes it, then, that among the principals whose services were acknowledged by Sir ROBERT NAPIER as having conduced to the success of the expedition, Dr. CURRIE has alone been excluded in the filtering process that the despatches underwent in their progress to concentration in the Houses of Parliament? With whomsoever the blame rests, the omission is a grievous mistake. The prospects of Army Medical Officers are already small enough in all conscience. Even with open competition there is some difficulty in "catching" a sufficient number of young men at ten shillings per day per head to fill existing vacancies; but, bye and bye, when the eyes of those self-same young men shall have been opened, when they see that they are shut out from the rewards of civil life, and not admitted to those prized so much in military, they will cease to take pride or to exert themselves in a position in which, whatever be their individual merits, whatever the services rendered by them, they meet with no other treatment than discouragement and absolute neglect.

THE ELECTION AT THE DUBLIN COLLEGE OF PHYSICIANS.

ON Friday next, the 24th instant, the President and Fellows of the King and Queen's College of Physicians in Ireland will proceed to elect a King's Professor of the Practice of Physic on the foundation of Sir Patrick Dun, under the provisions of the School of Physic Act of 1800, and of the amended statute—the School of Physic Amendment Act of 1867.

We have on more than one occasion adverted to this matter, and as our readers are by this time tolerably well acquainted with the facts of the case, we need not further advert to them now. We have every confidence in the electors, and we are convinced that each one will vote according to his solemn oath, and execute the trust reposed in him to the best of his judgment, and for the honour and dignity of our profession.

There is, however, one point in connection with this election to which sufficient attention has scarcely been given, in our opinion, and it is this, the important, very important, question—how long shall the Professor hold his office?

The newly elected professor, according to the terms of the statute, will be chosen for seven years only; and, herein, we think, lies a very important consideration.

Hitherto, it has been customary to re-elect the Professors of the School of Physic at the conclusion of their Septennial terms, the Act empowering the electors to do so; but there is nothing in the terms of the Act to give rise to the idea that these professorships are *de facto* tenable for life.

When once a gentleman has been elected on the old custom, mooting this question, so far as he is concerned, would, of course, have a personal aspect; and, therefore, we disclaim any reference to existing professors in these remarks. Our idea is, that this election ought to be clearly understood to be in the strict terms of the Statute, for seven years only, and not for life; and that, at the end of that time, there should be a fresh *bonâ fide* election, open to the retiring professor, as well as to all other candidates.

The advantages of this are numerous.

If the professor has been found to be a man of only ordinary ability, a more able man can be put in his place, without any real or implied censure on him; while, if he has been found to be very able in the discharge of his professional duties, he need not fear competition.

Again, if a man be chosen because he is senior and experienced, he will, when too senior, give place to others before he becomes a clinical bore to students; while, if a man be chosen because he is young and active, he will, in time, give place to other young and active men, who will thus be not excluded from office for a long life-time, but will have a stimulus to exertion, and a strong motive for preparation for such frequently occurring vacancies.

A candidate for such a place may be too old to be chosen for a life-time, but not too old to be chosen for seven years; and a candidate may also be too young to be chosen for a life time, but not too young to be chosen after the lapse of one septennial period.

The Benchers of the King's Inns elect their professors for three years only, and several of the Dublin University professorships are only for a term of years.

If a man be chosen professor, and given seven years to make a name and position, he may, if successful, very well give place to another, who could thus have a similar advantage. Whereas, if he did not make a name and position in seven years, the School of Physic could well afford to supply his place with a better man.

The Professor of the Practice of Physic should not be a lecturer in stereotype, whose very sentences, by unceasing repetition, become butts for the wit and satire of the student.

NOTES ON THE ABYSSINIANS.

No. IV.

In our issue for the 1st instant we noted the deaths and funerals, and some of the treatment given to the sick among this curious and ancient people. We shall now note some facts in their religion and superstitions which have bearing on medicine. By profession the great majority of the nation are Christians, and they will not eat of meat slaughtered by any but a Christian hand. Their fasts are more numerous, perhaps, than those of any other Christian people, more than two-thirds of the year being assigned to more or less abstinence. In their fasting it is not sufficient to abstain from animal food only; during fast-time they neither eat or drink anything until late in the afternoon, and this (observes Mr. Parkyns) "is a severe mortification of the flesh in a hot and enervating climate. Many of their fasts are of long duration. The time of day when it is lawful to eat is decided by the length of a man's shadow, measured by his own feet, and varies in different fasts. Thus, the fast of Advent is during the last ten days of the month of October, and the whole of November, and during each day of that time till a man's shadow measures nine and a-half feet. Beside, there are all the other long fasts, and all Wednesdays and Fridays, making nearly 260 days of fasting in each year."

On the morning of St. John's Day the friends of persons "possessed of the devil," who have in vain tried all the ordinary remedies, take the patients into the country, where they are placed at a point where two cross roads meet. Then, in each case, as instructions have been received from the wise, "a white or a red sheep is dragged three times round him, and afterwards slaughtered 'in the name of the Father, and of the Son, and of the Holy Ghost.' The sign of the cross is then marked on the patient's forehead with the blood of the victim, which is left where it was killed, and the whole party returns homeward, being careful on no account to look back towards the sheep, lest by so doing they should disturb the devil, who is supposed to have left the man, and to be busy in eating the mutton."

The most common diseases appear to be tænia, quinsy, leprosy, scabies, and fevers. Even at the risk of quoting at full length, we deem Mr. Parkyns' remarks on these subjects —coming as they do from a non-professional observer, too important to be omitted.

In chap. xxxvi., p. 273, he says:—

"Tænia, or tape-worm, is on this account certainly the first to be considered, for the whole Abyssinian population may be said to be afflicted with it. Out of above forty persons, male and female, whom I had as servants at one time, only two were exempt, and I should say that this was a rather larger proportion than would be found in a general average of the people. The cause of this complaint has been frequently made a subject of speculation. By many it has been assigned to the eating of raw meat; by others again, to the great quantity of cayenne pepper used by the Abyssinians. The natives are in the habit of taking physic regularly once every two months to relieve them of this malady, but as yet they have no means of completely curing it, the head of the worm (as they say) remaining as a germ, from which link after link is formed, till a future dose is required. In this I believe European doctors are in nowise superior to the natives, for they have lately introduced into the Pharmacopœia one of the Abyssinian medicines called kousso. This is the flower and seed of a tree which grows abundantly in some parts of the country. In Abyssinia a supply sufficient for a man's life may be procured for the value of 6d., while in Europe a single dose, and that a very small one, costs several shillings. Besides this, the Abyssinians use the bark of another tree and the bulbous root of a small plant which, if it be not our common wood sorrel, is very nearly allied to it. One of these—I believe the bark—is reckoned much more efficacious than the "kousso," but is seldom used, from being supposed to be highly dangerous in its effects. The one is called 'basinna,' the other 'muitcha-muitcho.' Neither of these, however, is used when the kousso can be procured. The dried flowers are ground or pounded as fine as possible, and a strong infusion made, of which the patient takes more than half a pint fasting. About noon, when it has taken the required effect, a good quantity of beer or tedge is considered beneficial, on which account, if the sufferer be a servant, he begs for a supply from his master, or any friends who may be dining with him; coming round at meals, holding in his hand a small cross made of two bits of stick or straw, and exclaiming, 'For the sake of Mary, for the sake of the Saviour,' &c., when a horn of liquor is usually given him.

"Next is the complaint called 'hannat,' which is a glandular enlargement in the throat, ultimately forming abscesses, which increase to such a size that, if no means to cure them be taken, the throat is completely stopped up and the patient suffocated; this, after the tænia, is perhaps the most frequent malady of the Abyssinians. The premonitory symptoms are violent pains in the head, back, and legs, and much dizziness. The following remarks, taken from my original notes, will exemplify the treatment adopted for it:—'Tisphitou' (one of my servants), 'on his return from Mai Quollaw, was seized with the hannat; not having any of the preventive medicine, they twice took a good deal of blood from his head, but with no beneficial effect. The night before last he was obliged to be carried into the hut, being nearly senseless; the other servants urged him to have his throat examined, but he seemed reduced to that listless, apathetic state of mind in which we see people who are suffering from violent sea-sickness, for he begged to be left alone and not bothered; on being expostulated with, and the danger of delay pointed out to him, he merely said 'Oh, never mind; let me alone.' However, a soldier who happened to be in the village volunteering his services, and professing to be a skilful operator, we forced the patient's mouth open, and held him while the examination was going on. The throat was almost entirely closed, and, had the man been allowed to remain till the morrow, he would in all probability have died. The soldier, however, made short work with it; for, thrusting in his hand, he tore the swellings with his nail, and the patient, having ejected a quantity of matter and blood, was pronounced out of danger for the time. On the advice of the operator I gave him a good dose of jalap, and he ultimately recovered, though he remained in a very weak state for several days. Since his illness almost all of our people have suffered more or less from this same complaint. The preventive medicine which I alluded to is a sort of root, which is chewed in an early stage of the malady, and seems, when taken in time, to be a certain antidote. One symptom is extreme furriness of the tongue. The disease of which Mr. Salt (*vide* Valentia's Travels, vol. iii., p. 80) doubts the existence in Abyssinia is unfortunately only too prevalent; I myself have treated many cases of it, generally with much success where it was taken in time; but occasionally I have seen some most horrible instances where it has been neglected—living specimens, quite as fearful to behold as any of the models in the Musée d'Anatomie at Paris. That the Abyssinians appreciate the difference between it and the scorbutic affection with which Mr. Salt confounds it, is evident from their having distinct names for it. In Tigrè it is called 'fintàta;' in Amhàric, 'kitting;' and in the Galla language, 'fànto.' I have already mentioned that among the native remedies the flesh or blood of the wild boar is reckoned as one, probably, as I said, from their having seen the lard used by Europeans in the composition of mercurial ointment. They have several others, but none productive of good effect. Near Metemma, in the Nubian province of Berber, there is a sort of whitish-coloured earth, called by the natives 'toureyba,' which is used as a medicine in these cases, and I have been assured (even by some European medical men) with a good result: in Abyssinia they possess nothing so valuable. There is an old Armenian named Gorgorious (Gregory), who administers to sufferers, at a considerable charge, what he professes to be a certain cure. This is nothing more nor less than a dozen or two pills, containing corrosive sublimate, the recipe for which he, no doubt, obtained from some quack in Egypt. Though a rather dangerous medicine, this preparation of mercury might, in many cases, if properly administered, be beneficial; but with our friend, who never troubles himself either to examine his patient, or inquire how long he has been afflicted, simply receiving his fee and desiring the sufferer to take so many per diem till the box is finished, it is a case of 'kill,' perhaps, oftener than of 'cure.' The natives, too, are very difficult to deal with, for they cannot be made to understand that, where one dose will do them good, two may be injurious; nor are the blacks worse in this respect than the Turks, Greeks, or Egyptians—of which I have had many proofs.

"There is a sort of horrible scrofulous disease in all these countries, which causes the loss of the hands or feet. The people of Sennàr call it 'judàm;' I forget the Tigrè name. Elephantiasis is not so common in Abyssinia as in the low lands to the north, nor is the Guinea worm. I have never seen any case of the latter in this country, except in a pilgrim who was merely passing through. In the provinces of Sennàr it is called 'fràntite,' and its origin attributed to the black soil of the country; it sometimes appears in the arms or body, but most commonly in the lower part of the leg. The only cure is to wind the worm gradually out, taking great care not to break it, which accident might be productive of very dangerous consequences.

"Scabies is very prevalent, but I am doubtful if it is the same as that which is common with us. It generally fixes itself on the elbows, where it forms a large sore difficult enough to get rid of. It does not seem to depend at all on the habits of the person or on contagion, for I have known Europeans to have it without any assignable cause.

"The various fevers of tropical climates are tolerably abundant in Abyssinia, though principally confined to the low marshy districts just after the cessation of the periodical rains. The natives seem to have but one name for any fever caught in the jungle ('nedad'), whether it be common intermittent ague or the fearful bilious jungle fever; while those of a low typhoid class, which occasionally visit even the most elevated towns, often as epidemics, are called 'mitàt.' Local bleedings, aperients, and emetics are administered in these; for aperients they have certain herbs, but not an uncommon agent for producing both purgative and emetic effects is a large quantity of 'ghee' (clarified butter) and honey. Dysentery, and the other complaints of the same family, are by no means uncommon. This is the disease which is most fatal to Europeans in these countries: several Frenchmen have died of it in Abyssinia. The natives chew a root, in addition to the above-named medicines, for this class of malady. The root has a pungent taste, between ginger and pepper, and I really believe it did me some good on one occasion, when, not being able to have recourse to my own drugs, I was obliged to put up with those of the country. Small-pox is, I should say, not so uncommon here as in many parts of the world: it has visited Abyssinia, as an epidemic, once or twice in the last fifteen years, but, judging by the number of those who bear its traces, I should say, not very severely."

◆

Notes on Current Topics.

Royal College of Physicians of London.

BEFORE this meets the eye of our readers, the annual meeting for the election of Fellows of this College will, in all probability, have terminated.

Without any feeling of personal disrespect to the gentlemen nominated, we trust that the Fellows will, for a second time within a brief period, remind some members of the Council of the existence of such things as "daylight and fair-play," by refusing to endorse the selection they have made; or, failing this always painful means of even enforcing a principle, we trust that they will, at least, render the Council powerless in the future, to inflict further injury upon their tottering institution.

Medical Department of the Privy Council.

MR. SIMON, the Medical Officer, has published his tenth report, which forms a volume containing a variety of interesting and valuable particulars, which we can only briefly notice. It consists of two parts or divisions. The first relates to public vaccination, and to the causes and extent of local outbreaks of disease, from which we learn that the work of vaccination has been so far satisfactory, that gratuities were given to 231 vaccinators, amounting to £1824—the largest being £67, 7s. 4d., and the smallest only 15s. 4d. Winterton, Guilford, and Terling, where typhoid fever has been the prevailing disease, are the places to which the inquiries have been principally confined. The filthy state of the locality, and the culpable neglect of sanitary measures, were found to be the chief cause of the epidemic, except in Guilford, where the immediate cause of the outbreak was the impurity of the water-supply. The second part of the report details what Mr. Simon calls the "systematic proceedings" which have been pursued, "with the object of increasing our exact knowledge of disease." They include "An Inquiry by Dr. Buchanan, on the Relation of Phthisis to Dampness of Soil;" "An Inquiry by Dr. Sanderson into the Innoculability of so-called Tubercular Disease;" and "A Report by Dr. Thudichum on the Chemical Researches he has made towards obtaining a precise knowledge in those chemical aspects of pathology, where at present there is almost utter darkness."

Medical Candidates for Parliament.

DR. CHADWICK, whose recent munificent donation to

Bolton we had the pleasure of recording, is to be the Conservative candidate for the borough. Our own wish to see more medical men in the House is too well-known for us to need to do more than announce this fact. We sincerely hope that in all parts the profession will be awake to its own interests.

Besides the other names we have mentioned, it is now stated that Dr. Walshe, of University College, London, would be willing to contest a borough in the Liberal interest. We heartily hope some borough will at once secure so eligible a candidate. The other candidates talked of still make no sign.

Aneurism in the Army.

THE late Dr. John Davy, Inspector-General, in his work on "Diseases of the Army" (p. 372) gives a series of statistics of aneurism, from which the following information as to the rate of prevalence of, and deaths by, that disease, has been prepared, both these being recorded so as to represent 1000 mean strength for one year.

The ratio of deaths by this disease is according to him—

In the Cavalry	·31
In the Infantry	·14

According to stations the rates of admissions and deaths were as follows, namely—

	Admissions.	Deaths.
Jamaica	·32	·13
Windward and Leeward Islands	·20	·11
Canada	·15	·07
Nova Scotia and New Brunswick	·11	·07
Bermudas	·26	·17
Gibraltar	·57	·39
Malta	·33	·23
Cape of Good Hope	·32	·11

The above statistics refer to different periods; thus, as regards Gibraltar, Malta, Bermudas, Nova Scotia, and Canada, they embrace the period extending from 1837 to 1847 both inclusive, but as regards the Cape of Good Hope windward and leeward islands, and Jamaica, the period from 1818 to 1836 both inclusive.

The records available for reference do not inform us as to the locality of the aneurism or artery affected; this circumstance is, however, of the less moment, inasmuch as traumatic aneurism, if affecting the limbs, is not often fatal; while idiopathic cases of the disease, whether occurring in the external or internal vessels, are those by which mortality is in the great majority of instances occasioned.

The series of departmental blue-books enable us to give similar information with regard to the prevalence of, and mortality by, this disease among the troops in the United Kingdom, and in each of the three Presidencies of India. From these we select the statistics of the five years from 1861 to 1865 inclusive, and find the averages of admitted and died per 1000 of mean strength per annum to have been—

	Admissions.	Deaths.
In Madras	·51	·16
Bombay	·47	·24
Bengal	·39	·24
And in the United Kingdom	·37	·35

With reference to the latter, it may be mentioned that the yearly rates of mortality during the period have varied considerably. Thus, they were in 1861, 0·27; in 1862, 0·24; in 1863, 0·37; in 1864, 0·57; and in 1865, 0·37.

The statistics of the disease given below, as they refer to Ceylon, China, and Australia, are obtained from the returns of those places for the five years from 1861 to 1865 inclusive.

Following the manner of comparison already pursued, we obtain the following ratios, viz.:—

	Admissions.	Deaths.
Ceylon	1·12	·67
China	·28	·22
Australia	1·16	1·16

From these figures we find the somewhat unexpected result that at the Cape of Good Hope, where diseases of the heart are usually believed to be very prevalent, the ratio of deaths by aneurism is considerably less than in the United Kingdom, while the greatest rate of mortality from this cause is observed at places having such very different climates and circumstances generally, as Australia and Ceylon.

The Lothians' Medical Association.

WE have received the second annual report of this important association, and have great pleasure in observing the progress it has made, and the vigorous attempt it has inaugurated of placing the profession in a better position. The dispensary system in Edinburgh has been thoroughly investigated, and from the effect already produced we augur well for the future of the Association. The Committee seem to have felt very strongly the evils of too much gratuitous medical aid, and they very properly urge the objections that have frequently been pointed out, to making whole classes of artizans dependant on charity for medical relief in time of sickness. The improvidence of the working-classes ought not to be encouraged, and undoubtedly much has been done towards rendering them paupers in spirit, by teaching them to look for medical aid in the shape of charity. The committee report that the abuse of charity at the Children's Hospital is most conspicuous:—

> "There the general 'well put on' appearance shows the character of the class; sometimes they come attended by their servant maids, and many acknowledge that they have regular family medical attendants. The special character of the Institution is doubtless the cause of this, but there is on this very account the greater need for care and discrimination. No objection can be made to their applying there, in the same way as the higher classes would go to a consulting physician, but the same care should be instituted in the one case as in the other, of trenching on general practice, and those who have, or can afford to have, a medical attendant, should not be permitted to attend regularly, or to be attended at their own homes.
>
> "The pauper class, it is known, are no unfrequent applicants at the dispensaries, but as no systematic inquiries are made, their character is only occasionally discovered."

THE removal of the Medical Club to more capacious premises has been inaugurated by a dinner after the orthodox English fashion.

Sir William Fergusson occupied the chair, supported by Sir Charles M'Grigor and Sir Ranald Martin. The usual loyal and patriotic toasts having been duly honoured, the Chairman gave the toast of the evening—"Success to the Medical Club." He remarked that although the Club was only in the second year of its existence, it had by careful management and prudent forethought, acquired a position which would bear favourable comparison with any Club in London of a similar age.

The want of such an institution had long been felt, especially when medical reform occupied so large a share of professional attention. A club of this kind must, necessarily, in time exercise considerable influence upon the politics of the profession, for there could be no social life without political life. The opinions of the profession could not fail, through the medium of the Club, ultimately, to obtain increased weight and importance.

It is not proposed to limit the membership of the Club to doctors, but to admit gentlemen connected with science and literature generally. It may fairly be anticipated that the Medical Club will ultimately become the favourite resort of the scientific men in the metropolis.

Since the first establishment of the Club the number of members have continued steadily to increase, and we now muster about 700 names on the roll of the Club. To carry out all the improvements still in contemplation, it has been decided next year to increase the amount of the annual subscription. This step has always been in contemplation, and its adoption has often been urged upon the Committee by members of the Club, but it has been thought desirable to delay asking for such an increase until we were in a position to offer increased accommodation.

Sir William was repeatedly cheered during the delivery of his speech, and the toast was received with the greatest enthusiasm. With it was associated the name of Dr. Lory Marsh, to whose untiring energy the profession owes the establishment and much of the success of its Club.

◆

OVER-POPULATION AND PUBLIC HEALTH.

At a crowded meeting of the Dialectical Society, held in the Medical Society's Rooms on July 1st—Vice-President, Lord Amberley, in the chair—a paper was read by James Laurie, Esq. (formerly Inspector of Schools), "On the Happiness of the Community as Affected by Large Families."

Among those present were Dr. Steele, of Guy's Hospital; Mr. Cowper, of London Hospital; Mr. and Mrs. F. Malleson, Mr. Stirling, of New York; Dr. and Mrs. Edmunds, &c.

The author of the paper showed by reference to history, both from that contained in the Bible and in other works, that the constant state of human society had been one of continued struggle for existence, which had been caused by the well-known tendency of all organized beings, including man, to reproduce their numbers more rapidly than food can be obtained. The law of population, he explained, had frequently been alluded to by ancient writers among the Greeks and Romans—for example, both Aristotle and Plato had been fully conscious of this important truth. But it was not until the immortal work of Malthus, written about the commencement of the present century, appeared, that the question had been clearly understood; and it was now one of the most certain acquisitions of science that the human race has the power of doubling its numbers, by the mere power of fecundity it possessed, in twenty-five years, or less, when supplied with the necessary food. As a consequence of this law, Mr. Laurie added, it was impossible to get rid of poverty in old and long-peopled countries such as this without a most careful limitation of the size of families; and he quoted from the great work on the "Principles of Political Economy," by Mr. J. S. Mill, to show many fallacies were entertained on this question, persons actually contending that paupers in the workhouse should be allowed to engender hereditary paupers. After explaining that emigration did not go nearly fast enough to take off the surplus population of Europe, and adverting to the cultivation of waste lands and other so-called remedies for over-population, Mr. Laurie ended by saying that the least disagreeable of all the ways of preventing over-population and poverty seemed to him to be the small family system prevailing, to a certain extent, in France and elsewhere.

Mr. McSweeney related a conversation he had had with a country labourer in Salisbury Plain, who said that he had only 8s. a-week, and on this kept a wife and three children. This deplorable state of matters was owing, in great measure, to the fact that the people of this country were a landless people, and to the existence of large tracts of country taken up by the hunting-grounds of the aristocracy. He maintained that new laws were required to make this evil cease.

Mr. Levy said the causes of the poverty and misery of the poorer classes were not fully realised by the majority of the members of society. He avowed himself a complete convert to the opinions put forward by the author of the paper, which, he believed, were undoubted truths. Mr. Malthus's law of population was the explanation of the poverty which existed in industrious countries. The different tenures of land much tended to obstruct a clear view of the subject. Thus, the cottier tenant of Ireland having always to pay a mere nominal rent, had no inducement to be prudent in the matter of multiplication of children, since his real rent was never more than he could afford to pay after furnishing a scanty meal of potatoes to his family out of the produce of the soil. As to the way in which the limitation of families should take place, he (Mr. Levy) did not think, with many, that each family should only have two or three children. Delicate persons would be better without any children, and the robust and capable ought to have the privilege of engendering a larger number than the average.

Dr. Chapman accepted the law of Malthus as a scientific truth, and thought there was no doubt that the human race was capable of doubling its numbers in circumstances in periods of twenty-five years by the mere powers of fecundity inherent in it. He thought, however, that the subject required also to be considered from a national point of view, and contended that if the superior races, such as the English, were to restrain their increase, the inferior races would fill up the vacant spaces on the earth to the detriment of the prospects of the race. The tendency to procreation helped us to keep down the inferior races, and thus, with the palliative of emigration, he thought that the "struggle for existence" was, on the whole, beneficial to mankind. Why not carry all our surplus population to the Colonies? The land tenure was capable of great improvement, and he held that the State should be the land-owner, which would be a great remedy for poverty at present. The principle of co-operation, too, would tend to palliate the evils of poverty. Lastly, he had, some years ago, emitted a theory, afterwards taken up by Mr. H. Spencer, that, just in proportion as the members of the human race became more cultivated, so did their tendency to reproduce themselves become lessened. Hence, probably, as civilization advanced, the mere animal propensities would become more easily kept in abeyance, and poverty, arising from our over-population, would cease.

Mr. Bradlaugh thought that no subject could possibly be more interesting than that before the society. He thought there was no doubt that population had a tendency to increase more rapidly than food could be obtained, and hence the frightful destitution which was so commonly witnessed. With regard to the inferior races, as Dr. Chapman urged, being alone kept from having large families, they were the very persons who at present had the largest families: and, again, no person would submit to be told that, because they belonged to an inferior breed, they should not have any children. The speaker said that many of the flower of the working classes in all parts of England were agitating this question; and he would add that, although the question of large families was a delicate one, the sufferings and misery of the poorer classes was so great that it was quite essential that the subject should be thoroughly gone into.

Lord Amberley said the subject brought forward by Mr. Lawrie was of first-rate importance. There was no doubt that prevention of over-population was by far the most satisfactory method of attacking the evil. How was this idea to be best spread among the poorer classes? He was glad to hear from Mr. Bradlaugh that the working classes were beginning to debate this vital point. Unfortunately the influence of the clergy in common with that of society, and the natural passions of mankind, were opposed to the prevention of over-population. He believed, indeed, that women would naturally have a stronger feeling against large families, had they any say in the matter, and if their opinions were more heard. He was truly glad to hear the credit of the discovery given to the illustrious Malthus. Like all other discoveries, there was something wanting in the working out of the details of Malthus' views, and in the ways in which over-population could be prevented with the least pain and discomfort. He ventured to think that the propositions of Mr. McSweeny, that the evils of over-population could be remedied by taking the hunting-grounds of the nobility, were erroneous. If it would do so, he, for one, did he possess such a park, would gladly part with it to do away with poverty; but, in fact, population would swallow up such small gifts in a few years, and leave only fewer open spaces for all to enjoy. Emigration was good, but not rapid enough to relieve the pressure caused by rapid multiplication. The practical conclusion from all of which seemed to him to be, that Mr. Malthus was correct, and that, if ever we are to escape, as a nation, from poverty, it must be by the limitation of the size of our families. He (Lord Amberley) objected to celibacy; we all naturally objected to war and famine. Well, then, the only remaining alternative seemed to him to be small families; and after all it turned out to be a medical question how this could best be accomplished without injury to the health. He wished much he could hear the proposals of the medical men in the room as to the best means of limiting numbers. In America ladies were in the habit of keeping back their families, but the methods they employed seemed to him to be dangerous to health. Hence he should much like to hear a discussion as to whether some innocuous measure might not be discovered. It was remarkable that the subject should have first been taken up in America, where it was not so much required as it was here.

Mr. **Rigby Smith** observed that he was completely convinced of the truth of the Malthusian law of population, and also quite convinced of the inadequacy of any alteration in the rapidity of emigration to cope with the rapidity of increase of the race. He, therefore, believed that the existence of large families was an immense evil. He would add that, at present, it was by no means the best portion of the race which increased and multiplied too fast; it was precisely the opposite of this. Witness the celibacy of the barristers and of the upper and educated classes, and the rapid multiplication of the uneducated classes.

Dr. **Charles Drysdale** said he would not assume that all in the room agreed with the law of population, according to Malthus. He believed it was but proved by the following facts:—During the years from 1790 up to 1810, there was scarcely any emigration into the United States of America, and yet the population there nearly doubled itself in these twenty years. Now, in Great Britain the greatest rapidity of multiplication ever known—*i.e.*, from 1800 to 1853, had caused the population to double only in 53 years. In France the rate of increase of late was almost null. In Turkey it was calculated that it would require 555 years for the population, at its present rate of increase, to double itself. Now, it was evident that if in France, for example, the population did not double itself so fast as in the United States from 1790 to 1810, it must be because it was checked in various ways. And, on enquiry, it would be found that in France, as in England—(1) Marriages were contracted later than in America. (2) Wages were far lower in France than in the United States. (3) There were far more prostitutes in France than in the United States. (4) There were fewer children to a family in France than in England, or, *a fortiori*, in the United States. Lastly, a vast number of children died from privations and poverty. If any person would calmly survey these facts, he could not, Dr. Drysdale thought, avoid the conclusion come to by Mr. J. S. Mill, Lord Amberley, and others—namely, that since it was perfectly impossible for the inhabitants of old countries, such as this, to double so fast as in new states, they should earnestly endeavour to find out what was the least disagreeable way of checking their over-population. The sorrows attending poverty, the diseases caused by bad living, the fevers and consumption caused by overcrowding and town life, were deplorable and distressing to contemplate, and so were the fearful pestilences, such as the plagues and cholera which so decimated the ill-fed districts of our European cities. Then, again, wars were hideous evils, and would not cease as long as misery was so common. The wretched and the poor were ever the tools of tyrants, and that fraternity which all the good desired would never arrive so long as men were so poor. He, therefore, admitted with Lord Amberley, that the question was mainly a medical one—viz., how could married persons limit the number of their offspring without injuring their health? He thought this question required much calm thought and discussion, and meanwhile would only state that in France, a few years ago, he had in one hotel met with two young couples both married about 5 years, and both without children. On interrogation the same answer was returned by both husbands, that they were not rich enough yet to afford children. This was one solution of the difficulty of over-population, if not the best.

Mr. **Nasmyth** contended that the over production of children was, in a great measure, dependent on fashion. It was the present fashion in England to have large families, whilst in France, as everybody knew, a great number of persons thought it absolutely wrong to have more than two or three. This reduced the question to one of education, and he contended that it was disgraceful to educate children, as was done without any knowledge of physiology and anatomy. It seemed to him as if this were done simply for the purpose of keeping up a priesthood of medicine, and the sooner it was altered the better.

Mr. **Davis** contended that the cause of the poverty of the poorer classes in this country was not that they had too many children, but that the land laws were bad and required alteration.

The debate was adjourned until the 15th July, at the motion of Dr. Roberts.

Summary of Science.

(*Specially edited and Compiled for the Medical Press and Circular.*)

By C. R. C. TICHBORNE, F.C.S., F.R.G.S.I., Etc.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

DR. CRUM BROWN'S PAPERS ON CHEMICAL CONSTITUTION AND ITS RELATION TO PHYSIOLOGICAL ACTION.

The investigations of the above gentleman and Dr. Frazer are intended to open a most important field of inquiry, but one of which there is none so difficult or so hidden in its manifestations. The mode in which these gentlemen proceed is the following:—They take a certain class of compounds the physiological action of which is well-marked (strychnia, brucia, thebaia, morphia, codeia). These alkaloids contain a similarly situated atom of nitrogen, which is capable of being changed as regards its atomicity or relation. The salts of these alkaloids do not differ from the alkaloids themselves, because the combination is not of a very stable kind, and because the acid produces no particular molecular change in the alkaloid itself. They therefore combined the strychnia with methyl, and produced a stable compound—methyl-strychnium, first studied by How and Stahlsmidt. Large doses of thirty grains of the methyl-strychnium salt produce no action upon rabbits when administered by the stomach; fifteen grains killed, however, when injected by the skin. But instead of violent tetanic convulsions, a condition of general paralysis is observed.

On examination, paralysis was proved to have been produced by the destruction of the power of the terminations of the motor nerves to receive the stimulus and transmit it to the muscles.

Strychnia produces tetanic convulsions by exciting the nerve-centres in the spinal chord; but the methyl compound produces paralysis, and does so in a very remarkable way.

The same change is produced in every alkaloid examined which has an action like that of strychnia.

ANALYSIS OF POTABLE WATER.

Some considerable discussion has arisen in scientific circles upon the above subject. The analysis of water has been thoroughly investigated by Dr. Frankland, who read before the Royal Institution a *resume* of his experiments, from which we have culled the following important observations:—

The author, in his lecture, exhibited the test usually employed for determining the nitrogen existing as nitrates and nitrites, which, as he said, is called combined nitrogen. But it is not organic nitrogen, although it has in most cases been derived from organic matter. It is also necessary to determine how much nitrogen is present as free ammonia. This is done by what is called Nessler's test.

Dr. Frankland divides the mineral portions of the water into three subdivisions, viz.:—

1. Soap-destroying substances.
2. Mineral compounds, constituting chiefly the skeleton of the decomposed sewage, or manure.
3. Poisonous substances, such as arsenic, copper, and lead.

The first communicate to water its hardness. Medical arguments have from time to time been advanced, now in favour and now against both hard and soft water—*i.e.*, it has been stated that hard water is necessary for the formation of bone, &c. Again, M. Belgrand states that the inhabitants of the hard-water districts of France notoriously suffer from carious teeth. But as regards the enormous advantages of soft water for washing and manufacturing purposes, there is no difference of opinion.

The saving of soap, by the introduction of the Loch Katrine water, is estimated by Dr. Frankland as £36,000 annually. "My own experience," says the author, on referring to the hardness of the London water (which is temporary), "leads me to the conclusion that the advantages of temporary over permanent hardness has been considerably overrated. In reality water used for domestic purposes is even when used hot, either not heated to the boiling point, or is boiled far too short a time to remove more than a small proportion of its temporary hardness. Thus, water drawn from the kitchen boilers of the Athenæum Club, was usually almost as hard as the cold water with which they were supplied." We give three examples from a list of some of the waters, as representing the importance of the hardness of waters :—

Soap destroyed by 100,000*lbs. of water.*

Thames water	212
Glasgow (Loch Katrine)	4
Lancaster	1

The putrescible nitrogenous organic matters present in water, consists of the mineral compounds constituting chiefly the skeleton of decomposed sewage, or manure. The putrescible nitrogenous organic matters present in water or in the soil through which water percolates, undergo gradual oxidation and decomposition, by which their carbon and hydrogen are converted into carbonic acid and water, and their nitrogen into ammonia, nitrous, and nitric acid. The last three constitute a record of previous contamination with putrescible nitrogenous organic matter. Dr. Bence Jones has, however, demonstrated that rain water always contains about ·032 parts of ammonia in 100,000 of water, therefore, this amount must be deducted from that found on analysis, as nitrogen derived from ærial sources. The remainder, if any, represents the nitrogen derived from putrefied nitrogenous matter in the water.

The following paragraph is of considerable importance, and we therefore give the author *verbatim*:—

"To express this (sewage contamination) in terms of some known standard, I employ average filtered London sewage, which contains 10 parts of nitrogen in the form of putrescible organic matter in 100,000 parts. Thus, a water which contains one part of nitrogen in 100,000, as nitrous acid, nitric acid, and ammonia would contain in 100,000 parts the remains, or skeleton of, an amount of putrescible organic matter equal to that contained in 10,000 parts of averaged filtered London sewage. Such a water, therefore, is said to have a previous sewage contamination of 10,000 parts in every 100,000 parts. But it may be asked is this a true record of the previous history of the water in this respect. I believe that this nitrogen as truly represents a quantity of previously existing putrescible organic nitrogenous matter, as that the bones of a megatherium demonstrate the previous existence of an individual of that species—just as chemical and mechanical agencies have broken up and dissipated the remains of millions of animals during long geological periods—so does the action of growing plants, and, perhaps, also of living animals, remove from water in a few hours or days some portion of this skeleton of previous putrescible organic matter. Thus, by storage the East London Company reduced the sewage contamination of the River Lea from 2000 down to 230 parts in 100,000.

These skeleton compounds are in themselves innoxious, but inasmuch as they show, that the water has been in contact with animal refuse, they bring a heavy charge against it.

Refuse animal matters are known to contain what is hurtful to human life. This hurtful matter is believed, on good evidence, to consist of spores, or germs of organisms; which are capable of producing in man such diseases as cholera, typhoid fever, and dysentery.

No practical process is known by which these spores, once introduced into water, can be again removed, or can have their vitality destroyed. Filtering will not do it; boiling, even for several hours, cannot be relied upon for the destruction of such germs, some of which have recently been shown to retain their vitality after four hours' boiling.

As regards the third class, or poisonous substances, such as arsenic, copper, and lead—these substances are only likely to occur in waters connected with mineral works.

Dr. Frankland states that the presence of a minute quantity of phosphate of lime prevents the water from acting upon lead.

Mr. Simmons, the medical officer of the Privy Council, says—that the person who contracts cholera in this country is, *ipso facto*, demonstrated with almost absolute certainty to have been exposed to excremented pollution, that what gave him cholera was mediately, or immediately, cholera contagium discharged from another's bowels. Excrement, sodden earth, excrement reeking air, excrement-tainted water, these are for us the causes of cholera. That they respectively act only in so far as the excrement is cholera-excrement, and that cholera-excrement, again, only acts in so far as it contains certain microscopical fungi, may be the truest of all true propositions; but whatever be their abstract truth, their separate application is impossible. Nowhere out of Laputa could there be serious thought of differentiating excremental performances into groups, diarrhœal and healthy, or of using the highest powers of the microscope to identify the cylindro-tænium for extermination. It is excrement, indiscriminately, which must be kept from fouling us with its decay. The way in which the southern districts of London have gradually gained comparative immunity from cholera, in proportion as their two water companies have ceased to distribute sewage-tainted water among them, is a matter of history.

BLACK VARNISH.

The Paris correspondent of the *Chemical News* mentions the following curious optical experiment. In a litre of alcohol, 12 grammes of aniline blue, 3 grammes of fuchsine (red), and 8 grammes of naphthaline yellow are dissolved. The whole is soluble, or nearly so, in less than 12 hours. One application renders a white object ebony black; the varnish can be filtered, and will never deposit afterwards. The three colours are not destroyed, for each can be separated by analysis with their characteristic properties.

CARBOLIC ACID.

Dr. Glover, of Millbank Prison, was sent down to Terling by the Home Secretary, to superintend the application of disinfection by carbolic acid to this town. His visit was in consequence of an epidemic of intestinal and typhoid fever prevailing in the village. In his report, he says that incredible quantities of fœcal matter had accumulated in uncovered cesspools, open ditches, &c., and had soaked into the soil. A strong solution of carbolic acid was distributed over the entire village. Large quantities of the solution were poured into the cesspools, and it was freely applied to the filthy yards, courts, and stagnant ditches, by which many of the houses were surrounded. Many of the inhabitants at first fancied the smell of the acid produced headache, and for some few days the medical officer and inspector of nuisances were most unpopular people in Terling. We can well understand this, as in the report it is described that the village was soaked with acid, and the atmosphere became highly charged with its vapour.

Out of a population of 900 persons 300 had been attacked by typhoid fever since 4th December, and of this number 41 died. Fresh cases continued to occur daily up to the end of February, while only two persons have been attacked since the 1st of March. The carbolic acid was first used on the 17th of February. The author of this Summary is only too glad to adduce another practical instance of the value of this powerful antiseptic, which he considers he was instrumental, in a great measure, in bringing before the Dublin public.

SOLUBILITY OF OXIDE OF IRON.

M. Jeannel states that the principal cause, if not the only cause, of hydrated sesquioxide of iron being more or less insoluble in water is due to the presence of a small quantity of sulphates. A new compound indefinitely soluble, which might be named ferric chloroxide, is easily obtained in solution or in the solid state. This compound is represented by perchloride of iron, $Fe_2 Cl_3$, and an indeterminate quantity of sesquioxide of iron, $Fe_2 O_3$. M. Jeannel says that he has prepared in the cold a stable aqueous solution, containing nine times the iron contained in the officinal solution. This solution would be found specially advantageous in checking hæmorrhage. The solution possesses in the highest degree the property of coagulating albumen. It is decomposed by sulphuric, citric, or tartaric acid, and is even decomposed by a few drops of concentrated nitric or hydrochloric acid.

GAMGEE'S EXPERIMENTS UPON BLOOD.

On using nitrites as a reducing agent, arterial blood assumes a chocolate colouration, and the spectrum, when viewed, is found to have been converted from that of scarlet cruorine to that of acid hæmatin. When sulphate of ammonium, or a reducing solution of iron is added to a blood solution, which has been acted upon by nitrites, all effects of their action disappear, and the solution again possesses the spectrum of oxidized blood-colouring matter, although precautions have been taken to exclude atmospheric air. The continued action of the reducing solution then leads to the reduction of the blood-colouring matter, which, when shaken with air, again yields the perfectly normal spectrum of blood. It would therefore appear that when nitrates act upon the blood-colouring matter, they do not decompose it, nor thrust out or remove the loose oxygen with which it is combined.

The gases of both normal blood and blood treated with nitrites were boiled in vacuo, their amount estimated, and their composition determined. It is shown that when blood has been acted upon by a nitrite, the amount of oxygen which can be removed by ebullition in a very perfect vacuum is immensely diminished, the greatest difference being perceived when the nitrite has been in contact with the blood during the longest period of time.

Although blood which has been acted upon by nitrites has, to a great extent, lost its power of absorbing oxygen, it still retains the property, which normal blood possesses, of ozonising the atmosphere. Oxygen-nitrite blood reacts with guaiacum paper exactly like normal blood, and when added to a solution of peroxyde of hydrogen it causes an evolution of oxygen.

The changes in the optical properties of blood are shown to be due to the formation of compounds of the nitrite used with oxidized hæmoglobin. These compounds, with the exception of that with nitrite of silver, presented the same crystalline form, colour, and spectrum wherever the nitrite was employed. The author obtained compounds with nitrite of sodium, potassium and silver, and nitrite of amyl. From the researches of Hoppe, Leyler, and Preyer, hydrocyanic acid possesses the property of forming compounds with oxidized hæmoglobin.

Foreign Medical Literature.

AN ABSTRACT OF DR. WESTPHAL'S PAPER ON THE GENERAL (PROGRESSIVE) PARALYSIS OF THE INSANE.

UBER DEN GEGENWARTIGEN STANDPUNCT DER KENNTNISSE VON DER ALLGEMEINEN PROGRESSIVEN PARALYSE DER IRREN.

By Dr. WESTPHAL,

LECTURER AT BERLIN.

(*Journal für Psychatrie.* 1868.)

THE disease is known under various terms as paralysie générale incomplète (Delaye), paralysie générale des aliénés (Calmeil), paralysie générale progressive (Requin, Sandras), folie paralytique (Parchappe), etc. Westphal first reviews the clinical symptoms of the disease, and afterwards the anatomical lesions. Respecting the former, we find certain disturbances of motility which formerly were considered as complications of the mental disease. They were afterwards brought into closer connection with the psychic symptoms to form one group of symptoms of the disease (entité morbids).

As regards the *psychic* symptoms, the mania of ambition (Grössendelirium) was formerly, and even recently by some English writers, considered an indispensable stage (Bayle), which was followed by mania and dementia. But Westphal considers this opinion as erroneous, as all forms of mania are found in paralytic patients, viz.: melancholia, hypochondria, idiotism, etc., even one individual may suffer from them in turns. We might possibly assume a stage of depression preceding that of maniacal disturbance, as common in mental disease, by ranging passing states of anxiety and uneasiness under the head of depression, but even in the beginning the psychic symptoms differ from common cases. In common hypochondria or melancholia the intellectual faculties are not impaired in the commencement, but if a cure does not obtain, they after a certain and perhaps considerable time get lost in a rapid manner. But all the paralytic patients suffer from mental weakness in the beginning.

Further, melancholia, mania or hypochondria, are not always present, but only a certain weakness which increases gradually till it reaches idiotism. Next to these symptoms we find headache, often of a violent character, and neuralgic pains, most likely of cerebral origin. Though the mental faculties [illegible] a constant progressive impairment, there are exceptional cases where improvement seems to take place for a time.

The disturbances of *motility* regard principally the tongue, especially so far as the language is concerned, the muscles of the face, the extremities, and often also the sphincters of the bladder and rectum. The most characteristic and easiest to recognise is the impairment of the language. In the beginning a slight occasional difficulty is observed, though the language is fluent, as if the patient stumbled over a word, but this is so slight that it is overlooked; in other cases, the language becomes altogether more slow, emphatic-like, as if the patient spoke with a certain caution, and as if in a state of slight drunkenness. Later the language becomes stuttering and at last only inarticulate sounds are heard. The tongue may be seen tremulous, later the power of volition over it gets lost, for instance the patient when ordered to show it jerks it out and in. Similarly the muscles of the face are affected, the masticatory ones act involuntarily, and the teeth are fletched. Paralysis of the tongue and face on one side are rare, and follow a fit, they are of a passing character. The voice looses its timbre, becomes sometimes nasal without paralytic lesions of the apparatus becoming evident.

Complete paralysis of the muscles of the eye is not observed, but duplex vision is frequent. Inequality of the pupils is of no value for the diagnosis, an exquisite myosis is often found, so that the pupils are not larger than pins heads.

The limbs.—Some spoke of paralysis or imperfect paralysis, especially of the lower extremities, others (Bouilloud) objected to the term paralysis as motility and sensibility are retained, but the movements lack inordination. They are irregular and comparable to those of animals whose cerebellum has been removed. Westphal believes both opinions founded on fact, and consequently adopts two classes of paralysis, which may be followed up clinically. The first comprises those patients who have the gait of tabetic patients, they sway to and fro when the eyes are closed. The second ones do not lift the feet properly when walking, they have a shuffling gait, making small steps and with widely separated legs. It is to be noticed that all the patients when in bed are able to execute movements, only at a late stage also this faculty is lost.

But though the disturbances of motion are usually more general, it happens sometimes that more or less complete paralysis of one limb or one side of the body occurs. These patients suffer at a later stage from involuntary evacuations of bladder and rectum; but it is not clear whether this is owing to paralysis or idiotism. In some cases, the disturbances of motility are so little manifest that we might speak of *latent* paralysis.

The impairment of *sensibility* is more difficult to describe and elucidate, as the answers of the patients are not reliable.

Elepsiform or *apoplectic* fits play a considerable part in the development of the disease. Loss of consciousness may be complete or incomplete—and giddiness, tumbling to one side, convulsions or passing paresis of one side of the body, or both. The language especially is defective after the fits, by the facialis and hypoglosus suffering. The psychic state is much worse after a fit.

Nature of the disease.—Bayle considered it a chronic meningitis, the symptoms depending upon different stages—viz., stage of monomania, mania, and dementia. But Westphal showed that, in reality, they do not exist. L. Meyer based the symptoms on the condition of the temperature, acute attacks being accompanied by high degrees of temperature. But Westphal thinks that the maniacal fits are in no distinct relation to the temperature, which is often increased by inflammatory diseases, and the temperature also varies without any known cause. Westphal also denies that purulent meningitis can be deduced from the presence of the whitish spots in the membranes. He also objects to Parchappe's affection of the cortical substance, especially the median one, as not proved. Rokitansky believed in hyperplasia of the cortical substance with amyloid degeneration. Westphal spoke of transformations of the walls of the blood-vessels which thicken. Robin and Lockhart Clarke examined the adventitia of the vessels, and came to the conclusion that in most cases that which had been considered pathological was a normal state, the latter believed to have found ectasiæ of the vessels. Virchow had seen them previously, and not considered abnormal. Westphal admits that the brain of the insane has sometimes a dark violet colour owing to congested blood-vessels, but he does not consider it necessary to admit newly-formed blood-vessels for explaining this condition, with some others (Mettenheimer, L. Meyer). Moreover, the cortical substance is often very pale.

Westphal once saw genuine inflammation of it in its first stage. A phthisical patient had symptoms of congestion with transient loss of consciousness, he got a little better, but worse again on the second day of the evening of which he died. A portion of the right hemisphere was found enormously swelled at the post-mortem, and there were numerous small blood extravasations. Such condition is never found in the brain of paralytic patients.

Others considered changes of the ganglion cells as originating the disease, but Westphal cannot confirm either Meschede's congestive imbibition, or Tigge's cellulous hyperplasia, or Virchow's and Mannkoff's fatty degeneration. Westphal admits that he is unable to give any explanation respecting the substance. As for the membranes, they often offer changes, but these are also found in other nervous diseases. Atrophia cerebri is likewise associated with progressive paralysis, but not less with other affections.

Westphal, without denying that Toffe drew first attention to the affection of the spinal cord in a more general manner, and without special cases, believes to have first clearly demonstrated that the cord is generally diseased in paralysis. He subdivides the affections of the cord thus: (1) Affection of the posterior tract from the neck down to the lumbar region. (2) Affection of the posterior portion of the side tract to the same extent. (3) Mixed affection of the posterior tract, and the posterior portions of the side tract. Pachy meningitis may or may not be associated with these lesions. The posterior tract wastes, owing to a considerable loss of nerve elements, they are replaced by a substance of connective tissue, which is interposed between the nerve tubes. The latter are either narrow, or of normal size, or very broad. This condition is most pronounced at the periphery of the posterior tract, especially in Goll's tracts (Keilstränge). There is no constant difference between the superior and inferior portion of the tract. This state is found in the medulla when hardened. In fresh specimens fatty granules and corpora amylacea may be found. Things are otherwise in the second and third affection. Free corpuscule cells are in fresh specimens, and the condition of chronic myelitis obtains. In the first-named class, generally the upper portion only of the posterior tract suffers.

The degeneration may be followed into the medulla oblongata, but does not reach beyond the fourth ventricle.

The connection between the affection of the medulla and the brain is not yet demonstrated. No constant extension of a morbid process from the brain to the cord, and *vice versa*, could be deduced from the anatomical changes, nor from the clinical symptoms during life. We may only assert that the psychic disturbance is generally observed at a later stage than the affection of the spine. Where psychic symptoms are the first, it is even more difficult to prove that the spine gets degenerated at a later stage, because the latter affection may exist latent for a long time. We are, therefore, at present entitled to consider both affections as independent from each other. Tabes dorsalis (locomotor ataxy) or grey degeneration of the posterior tract (Westphal's affections, No. 1) was formerly considered an independent affection of the spine, without the brain suffering, but Westphal believes it only relatively independent, as it occurs in the said peculiar connection with brain disease, with typical symptoms. The atrophy of the optic nerve, as observed in locomotor ataxy, and in progressive paralysis, points in the same direction. Epileptiform and apopletic seizures were likewise observed in grey degeneration, without mental disturbance, and with it. Therefore Westphal concludes that a certain disposition obtains of the nervous system, in consequence of which sometimes the spinal, at others the cerebral portions, at others, again, peripheric nerves suffer in succession, or simultaneously.

Correspondence.

REFORM IN THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Reform has been the cry for years in the political world, and I think the medical world may echo the same, with not only fairness to themselves, but with justice to the public—inasmuch, as what tends to advance medical interest, must react beneficially on them likewise. In general medical politics there is ample scope for reform; but when we consider the manner of election of the representatives in the Medical Council of the various universities and licensing corporations, reform is especially needed, if it were only for one thing, "to get the general practitioner represented."

The major part of the profession consists of general practitioners, and this class—for whom the Medical Council was thought to do, or rather it was anticipated it would do, a very great deal—is entirely ignored, having no representative in such Council: because the councillors representing each university and college are elected by the various officers who compose the committee or council of such corporations, to the entire exclusion of the holders of their various degrees or licenses. Now, such representatives being generally either pure physicians or pure surgeons, they are well calculated to look after their own interest or the *interests of the corporations they represent;* but what do they know? What can they know! of the everyday wants of the general practitioner of medicine and surgery? The general practitioner ought to be represented in the Medical Council. How is it to be done? I see by your admirable leader of this week, Dr. Andrew Wood proposed direct representation by increasing the number of councillors from men chosen by the profession, which must add to existing expenses; and surely they are large enough already—nay, too large, if compared with the real good the medical man has received for his £5 registration fee. Quackery is as rife as ever, and the public are very little wiser in matters medical now than they were prior to 1858.

Dr. Andrew Wood's proposal is fair and just, and he deserves the thanks of the great body of medical practitioners for it; but, for my own part, I hope to live to see the day when the proposal of Dr. Prosser James, to allow those who hold the diplomas of the various corporations to elect the representatives of such corporations, will become the law of the land. It is only fair and right that the Doctors and Bachelors of Medicine should each have a vote for electing the representative of their university in the Medical Council, and the Fellows, Members, and Licentiates of the three Colleges of Physicians and Surgeons, not forgetting the Faculty of Physicians and Surgeons of Glasgow, and the two Apothecaries' Halls, should enjoy the same privileges. If such were the case, I think the profession would reap great and decided benefit. Men would stand a chance of being elected, who might fairly be depended upon for doing justice to, and advancing the interests of, not only the select few, the chosen of the various corporations, but of the hard-working—in many cases overworked—and underpaid general practitioners. It might be that such representatives would not be afraid of speaking boldly on many points of medical reform. In this one particular, as in all others affecting the well-doing of the medical profession, Dr. Prosser James has always shown that he has the interests of the medical man at heart; and now since he has been requested to become a candidate to represent the Universities of Edinburgh and St. Andrews in Parliament, I can only wish him every success, because I feel sure he will be the right man in the right place, and I sincerely hope and trust that all who have a vote for either universities, and who would like to see the profession well represented in the House of Commons, may come forward and vote for him—well bearing in mind that the more medical we have in Parliament the better, and now when we get a candidate so well up in the requirements of the profession, it would be a great pity not to secure his election, say nothing about the loss to the medical world.—I am, sir, yours, &c.,

Henry W. Williams, C.M., M.D.

THE CARMICHAEL PRIZE ESSAYS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the report of the proceedings of the Medical Council (in your number of July 8th), your reporter states "that Dr. Alexander Wood suggested that my letter on the recent '*illegal*' award of the Carmichael Prize should be referred to the Lunacy Committee, and that this recommendation afforded considerable merriment." Your readers will scarcely believe me to have been *so* "daft," as to have expected that this matter would have been investigated by this *corporate* council; their game is not among the *Tritons*, but I think it would have been more becoming on the part of Mr. Hargrave, the representative of the Dublin College, if he had *courted* inquiry instead of *suppressing* it.

I ask you in common fairness to publish my letter sent to you last week, and let your readers judge for themselves.—Yours obediently,

Edwards Crisp, M.D.

29, Beaufort-street, Chelsea, July 9, 1868.

The following is a copy of the letter above referred to:—

THE LATE ILLEGAL ADJUDICATION OF THE CARMICHAEL PRIZE ON MEDICAL REFORM AND MEDICAL EDUCATION TO ONE OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF IRELAND, MAY 1, 1868.

TO THE PRESIDENT AND COUNCIL OF MEDICAL EDUCATION.

Gentlemen,—In September, 1862, when your proceedings were closed to the medical press, I placed before you the leading points connected with the illegal adjudication of the triennial prize of fifty guineas at the Royal College of Surgeons of England, and the illegal non-adjudication of the Carmichael prizes by the Royal College of Surgeons of Ireland, believing that it was your special province to investigate such matters as related to *medical education*, and to scientific progress. As you have probably forgotten the circumstances, you will, I trust, pardon me for directing your attention to the subjoined brief recapitulation. In the first example, a prize was given to a gentleman (one of the adjudicators being his colleague) for an essay full of vital and unmistakable errors, nearly all of which essay (nineteen twenty-fifths) had been published before. This gentleman did not comply with one of the printed directions of the Council, and on thirteen different occasions, as shown by the pamphlet I placed before you, told his colleague, that he was the author of the essay.

The other example, which has an important bearing upon the complaint I now place before you, was that of the Carmichael Prizes which, according to the will of Mr. Carmichael, if not thought worthy by the Council in 1854, the grant might be *postponed* until 1859. I place the word *postponed* in italics. "The adjudication to be made by the Council. The competitors to send in their essays three months before the first Monday in May, upon which day the Council shall pronounce judgment" (see Mr. Carmichael's will, *Dublin Medical Journal*, 1850, p. 409).

Notwithstanding these injunctions, the Council deputed three of their number to adjudicate, and although there were several candidates, Dr. E. Lee,[1] an old medical reformer, and one faculty advocate, Mr. Dale, of Plymouth (both which gentlemen have published their essays), Dr. Ansell, myself, and others, all I believe Englishmen, the prizes were illegally withheld, and no public report made by the three adjudicators. In your reply to my letter, you said "that the matter did not come within your province." I now make bold to bring the subject in a new dress; one in which the corporate habiliments are of the same colour, but the hue is more glaring and offensive.

In 1862 I protested against the legality of the proceeding: the leaving a political matter, to the judgment of *three persons*, especially in a country like Ireland where politics and religion exercise such a potent influence. Mr. Carmichael (as shown by his will) *never intended that the adjudication should be left to a small section, but to the council at large.*

But, gentlemen, as regulators of medical education, and as censors of medical honour, what think you of the recent adjudication of this prize to an *adjudicator*, one of the Council of the College, who in his *corporate capacity* (Medical Press and Circular, May 6th, p. 410) moved that the amount of the prizes should be doubled; but who, to use the words of the same Journal, tried for this prize in his *private capacity* (June 17th, p. 525.) According to the will of Mr. Carmichael, *not a word is said about the power of doubling the prizes after* 1859.

Gentlemen, these are the first[2] Carmichael prizes that have been awarded, although they bear so materially upon medical education and the good of humanity; they are to be competed for, according to the will of Mr. Carmichael, every four years, and it is for this reason that I bring this subject before you again. As I have said before, it is one that especially comes within your province—*Firstly*, Because it particularly relates to *medical education;* and, *secondly*, because those who have the power to sit in judgment upon others, should be careful that their own acts should be free from corporate taint and corruption.

Professor Syme, one of your Council, in speaking of the Swiney Cup adjudication by the elect of the London College of Physicians, said in his essay on "Medical Reform," 1850, "That a College that supported their own President on, and identified themselves with, the perpetration on such an outrage on decency and propriety, could not be safely trusted with any power of controlling the members of a liberal profession." I am sure that on the present occasion I shall have the Professor's support.

But let me in common fairness ask how many of the Council of Dublin College may, in "their *private capacities*" compete for the prizes in 1871? especially if the amount be doubled by themselves or their friends (£400, £200)? How can the Council, as directed by Mr. Carmichael, decide the question, if *even one of their body* become a candidate for the prize?

In justice to myself, I may add, that I have no pecuniary interest whatever in this matter, my essay now at the Dublin College of Surgeons (to be published by Dr. Mapother, the gainer of the first prize), and also the one sent in 1859, went far too deeply into corporate abuses, and into grades and distinctions in the very chambers of death, to lead me to expect even a commendation or an honourable mention. Indeed, according to the three adjudicators, who reported to the Council (Medical Press and Circular, May 6, p. 410), and whose judgment it would be treasonable to question, it, with the two other unsuccessful essays, "*did not come up even to the present advanced position and requirements of the profession.*"

I again ask you as a Council of Medical Education, and, to use the appellation of your President, as a "Commonwealth of Medicine," to investigate this important matter, so that future candidates for these prizes may know the amount of money they have to contend for, and the amount of corporate interest they have to contend against? Waiting your reply—I am, gentlemen, your obedient servant,

Edwards Crisp, M.D.

◆

GUY'S HOSPITAL, LONDON.

At a cost of about £30,000 the Directory of Guy's Hospital have determined on still further enlarging its capacity by accommodation for 160 new beds. This number is to be evenly distributed over four storeys, and the Ophthalmic department of the Hospital is to be transferred to the lowest of the four.

REJECTIONS AT THE LONDON COLLEGE OF SURGEONS.

Those who complain that the standard of medical education is lowered from the standard at which it should rest, can hardly charge the Royal College of Surgeons of England with accepting from its candidates an insufficient amount of professional information. Students appear, however, to have become imbued with a different idea, or else they are callous to the disgrace of being rejected for their ignorance, for the proportion of the "referred" to the "passed" candidates increases every year.

We are informed that out of 71 students who offered themselves at the last Anatomical or first half examination at the College, no less than 23 were sent back.

Whether teachers or students be responsible for this state of things, it shows a very dangerous indifference in the matter of education, and requires the most earnest attention of the profession.

◆

Medical News.

The Public Health.—We extract the following weekly returns from the Registrar-General:—In the week that ended on Saturday, July 11, 4354 births and 3168 deaths were registered in London and in 13 other large towns of the United Kingdom. The annual rate of mortality was 26 per 1000 persons living. The annual rate of mortality last week was 25 per 1000 in London, 19 in Edinburgh, and 16 in Dublin; 23 in Bristol, 26 in Birmingham, 27 in Liverpool, 36 in Manchester, 27 in Salford, 29 in Sheffield, 21 in Bradford, 30 in Leeds, 24 in Hull, 27 in Newcastle-upon-Tyne, and 27 in Glasgow. The deaths registered in London during the week were 1505. It was the twenty-eighth week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1379. The deaths in the present return exceed by 126 the estimated amount. The annual rate of mortality was 23 per 1000 in West London, 23 in North London, 25 in Central London, 28 in East London, and 26 in South London. The deaths from zymotic diseases were 582, the corrected average number being 430. Nine deaths from smallpox, 31 from measles, 39 from scarlatina, 14 from diphtheria, 42 from whooping-cough, 59 from fever, 300 from diarrhœa, and 19 from cholera were registered. The deaths from diarrhœa differ little in number from those in the preceding week. In the week which ended June 6, the deaths from diarrhœa were 27, in the four following weeks 31, 66, 171, and 286 persons died, and last week the deaths recorded were 300.

---

[1] See his letter, Medical Press and Circular, June 24th, p. 549.

[2] Four periods have elapsed since 1850.

STATISTICS OF INSANITY—The report of the Commissioners in Lunacy lately issued records 33,213 patients in the various institutions of England and Wales on the 1st of January, 1867, against 31,917 in the previous year. The inmates were distributed as follows:—25,680 in county and borough asylums, 2282 in registered hospitals, 2546 in metropolitan licensed houses, 2097 in provincial licensed houses, and 608 in naval, military, and State criminal asylums; of these numbers 27,361 were pauper lunatics, and 5852 private lunatics. Since January, 1867, 3572 were discharged as recovered, and 3365 died, including 25 by suicide. Of the 33,213 remaining in January, 1868, 3884 were deemed curable, 435 were found lunatic by inquisition, and 675 were criminals. In Colney Hatch Asylum the patients numbered 2036 on the 1st of Jan., 1867; the deaths during the year 1867 were 174, and the number discharged as recovered was 105; the admissions during the year were 306. On the 1st of January, 1868, there were 2035 patients, only 62 of whom were deemed curable. The principal causes of death were paralysis, epilepsy, phthisis, pneumonia, bronchitis, and exhaustion after mania. The mortality was lower than usual among females, but higher among males. No less than 380 applications for admission were refused from November, 1866, to November, 1867. The average numbers attending chapel were 270 men and 367 women; and not more than 300 altogether attended the general entertainments. In Hanwell Asylum the patients numbered 1723 on the 1st of January, 1867; the deaths during the year were 177, and the number discharged as recovered was 102; the admissions during the year were 344. On the 1st of January, 1868, there were 1723 patients, of whom 87 were deemed curable. At the visit paid by the Commissioners to this asylum in Dec., 1867, the records of employment showed that 789 of the patients were employed—viz., 239 men and 550 women; of the former, 60 worked on the farm and land, and 55 at trades; of the latter, 235 were engaged in needlework, 91 in the laundry department, and 23 in the kitchen, dairy, and bakehouse. The chapel attendance on Sunday was about 550. The asylum was much overcrowded, and the necessity of making further provision for the pauper lunatics of the county is a matter of pressing urgency.

MALVERN HOSPITAL.—The stranger, on approaching the Rural Hospital, will at once see that it belongs to the public—or that it is a public institution set apart for their use, but what he cannot conjecture unless some outside show be made. The building stands, as we before said, on elevated ground, and is surrounded with a rough stone wall, except in the front, and that is built and ornamented with red and blue bricks. There are two entrance gates, one for foot passengers and the other for carriages. The building and grounds occupy nearly two acres. That in front will be laid out with grass, shrubs, flowers, &c., and will contain a drive for carriages. The ground at the back will be used as a kitchen garden where the vegetables required by the servants and inmates will be grown. Round the building which is constructed with brick and Bath stone dressing, the latter used very sparingly, there is a protection wall to the foundation to keep it dry. The basement storey up to the ground line is of Malvern-hill stone, with brick quoins, and above are lines of red, white, and blue bricks. The arches and tympanum are set out with white and blue bricks, each arch being varied in style. The entrance to the building is by a flight of stone steps, over which is a hooded porch made of wood and covered with tiles, similar to those on the main building, which are capped with ornamental ones on the ridge. Over the entrance door is a fanlight leaded, the quarrys being of Cathedral glass. The door being opened, a vestibule or passage is entered six feet wide. It is stuccoed in imitation of Ashlar work. The floors of the vestibule and corridor are laid with Godwin's tiles, which he put down at half price. Passing down the vestibule, and on turning to the right, the corridor leads to the large ward for men. This is 17 by 26 feet, and 15 feet high, well lighted, and ventilated on north and south with cold air, and on the east with hot air. There are all necessary conveniences, water-closet, hot and cold water, and pipes for gas, when that is brought so far on the road. This room will accommodate four beds. Near to this is a smaller ward, similarly filled up, 13 by 16 feet, for two beds, and opposite this is the bath room, 9 by 11 feet, with all necessary appliances. The east side of the building will be occupied by men, while the west side will be apportioned to the females, and is in most respects similar to the men's side. Over the corridor and vestibule are groined arches, which give a light and elegant appearance. Opposite the entrance is the operating room, 20 by 14 feet, which is conveniently fitted up. It has two closets and a cupboard, one with hot and cold water, and one where the instruments will be kept. The ventilation and light are very efficient, as a large quantity of the latter comes in from a skylight. In the north west end of the corridor is a flight of steps leading to the basement part of the building, which is fitted up for attendants and nurses. The housekeeper's room is 17 by 26 and 9 feet high. It has convenient cupboards, piping for gas, and grate. It is flanked by a beer and wine cellar, fitted with zinc and glass, and necessary shelves and trams. The kitchen is 18 by 16 feet, and has a capital range with appliances for sending hot water all over the building. Out of it is a door leading to the scullery, where the force-pump, boiler, &c., are found. Adjoining this is the mortuary, coal celler, and small closet, the latter being flanked by a larder and visitors' waiting-room. The woodwork of all parts of the building is of the best red pine. The frames of the doors are stopped, champhered, and stained, while the panels are uncoloured, the whole being varnished.—*Malvern News.*

CINCHONA IN JAMAICA.—We learn upon reliable authority that there is every prospect that the attempt which is being made to add an important staple to the resources of the island of Jamaica in the cultivation of cinchonas will be attended with success. Under the direction of Mr. Robert Thomson operations were at first confined to propagation, which was undertaken in a systematic way in the early part of 1866. In March of the following year progress had so far been made that there were some 800 plants fairly growing. It was then decided to cultivate the trees on a more extended scale. With this view, plantations of from 100 to 200 acres were marked out in the Blue Mountain range and propagation was again carried on in contiguous sites ranging as regards elevation above sea level from 3500 to 6500 feet. The fact that certain plants, few in number it is true, had been growing here and there since 1861, and that one or two of these had actually attained the height of 20 feet, proved that the island in some parts was well suited to the growth of certain cinchonas. At the present time, as the result of the growth of cuttings and of seed furnished by Dr. Hooker from Ceylon, there are about 25,000 plants in vigorous growth. In May, 1867, a score of cinchona simarubra were transferred to a site of an altitude of 3700 feet, when they were about six inches in height; at the beginning of the present year they had actually grown to that of three feet. The larger number, however, of the 25,000 were in pots, 500 only had been planted out at a height of 5200 feet. Mr. Thomson, we understand, is fully impressed with the opinion that the cultivation of the cinchona will be "highly remunerative." He is not prepared to say which species is likely to be most luxuriant, but he has every reason to believe that the ultimate success in Jamaica "will not yield to that of India." These facts are of great interest, not only in regard to the increasing demand for quinine, but the commercial and consequent social improvement of the island. Should the government experiment be successful no doubt the landowners of the island will follow the example set them, and undertake the culture for themselves.—*Standard.*

TESTIMONIAL TO DR. JOHN HARLEY.—On Friday last a few of his old students presented this distinguished physician with a copy in silver of the Cellini Vase, bearing an appropriate inscription, on the occasion of his retirement from King's College, London, as Lecturer on Physiology in the evening class department. The testimonial was accompanied by a very flattering address. Regret is expressed on all sides at the inconsiderate manner in which Dr. Harley has been treated by the Medical Board of King's College, and it is pleasing to find the Doctor's students resenting the slight put upon him.

REMARKABLE AND CURIOUS CASE OF FOREIGN BODY IN THE LARYNX:

SEVEN ARTIFICIAL TEETH (SET IN GUTTA-PERCHA) HAVING ENTERED THE WINDPIPE DURING A FIT OF EPILEPSY: IMPENDING SUFFOCATION: TRACHEOTOMY PERFORMED: FOREIGN BODY EXTRACTED: DEATH THE RESULT OF A VIOLENT EPILEPTIC SEIZURE.

By HENRY GRAY CROLY, F.R.C.S.I.,
LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS;
SURGEON TO THE CITY OF DUBLIN HOSPITAL;
LECTURER ON CLINICAL SURGERY, ETC.

At 11 o'clock on the night of the 9th of July of the present year, I received an urgent message from Mr. Lyon, of Patrick-street (general medical practitioner), requesting me to visit Mr. ———, a *dentist*, aged 30 years, residing in Parliament-street, who had missed a set of artificial teeth from his own mouth, on recovering from an epileptic fit in the afternoon of that day, and who was then suffering from urgent dyspnœa.

Having placed in my pocket the instruments and appliances required for tracheotomy, I drove at once to the residence of the patient, and found him sitting up in bed suffering from croupy breathing.

In reply to my questions, he spoke in a whisper; I ascertained, on inquiry, from his wife, the following facts: Her husband had been the subject of severe epilepsy for sixteen years; he lost his teeth early in life, and before his marriage had an artificial set, which she was in the habit of removing when he was seized with a fit. The clasp of the upper set was broken, and through negligence had not been repaired; he was frequently attacked with epilepsy when in the act of operating as a dentist; he dined heartily at four o'clock on that day, and at five o'clock had a violent fit, and on recovering could not find the upper set of teeth belonging to the front of his mouth; he felt uneasiness in his throat; lost his voice, and had some difficulty of breathing; he searched his bed and room for the teeth but could not find them, and yet he would not believe that he had swallowed them. His wife sent for Mr. Lyon shortly after the occurrence, who, finding the patient's symptoms becoming serious, requested that I should be sent for. I proceeded to examine the patient in the following manner: I first passed the forefinger down to the entrance of the windpipe to ascertain if the foreign body lay across the opening. I then examined his chest carefully with the stethoscope, but could not discover any alteration from the natural respiratory murmur. I next drew forward the tongue, and introduced a long curved forceps into the larynx; this produced alarming dyspnœa. The patient vomited large lumps of meat and potatoes. I informed the patient and his wife that I believed the teeth were lodged in the windpipe, and that an opening should be made without delay into the air-tube to prevent suffocation. I also stated that if he got an epileptic fit while the foreign body lay in the windpipe he might be suffocated.

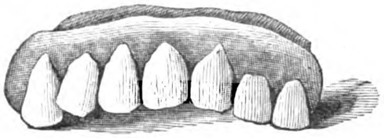
I had the advantage of a consultation with my able friend Mr. Porter, now President of the Royal College of Surgeons. He agreed with me as to the imperative need for immediate operative interference. In his presence I again attempted to feel the foreign body, with the aid of a long curved forceps, but was obliged to desist, in consequence of the urgent dyspnœa and struggling of the patient.

The necessity for the operation was fully explained to the patient and his wife. They agreed to our proposal, and I then proceeded to operate.

The patient was placed on his back on a table, as near as possible to a jet of gas which was over the mantel-piece. His shoulders were raised, but he suffered considerable dyspnœa when his head was brought backwards. His beard having been shortened, and the integument over the trachea steadily fixed, I made an incision in the median line with a scalpel, commencing about half an inch above the sternum, and extending nearly as high as the cricoid-cartilage. The fascia connecting the sterno-hyoid and sterno-thyroid muscles was divided on a director, and then, with the handle of the knife and the end of my forefinger, I quickly reached the tracheal fascia, which I scraped through with a director. Scarcely a drop of blood was lost. Enormous veins (the inferior thyroids), almost as large as goose-quills, were seen lying parallel to the trachea—these, with the sterno-hyoid and thyroid muscles, were carefully retracted by Mr. Porter. Having laid bare the rings of the trachea, which was very deep and small, I seized and raised the tube by means of a small hook, and with a narrow-bladed knife I cut a circular piece out of the trachea, as large as a sixpence.

The dyspnœa was relieved, and the air passed through the wound with a loud hissing sound. The windows were thrown widely open, and the patient sat up. I proceeded to search through the wound alternately with my finger, a bent probe, and a curved forceps, in every direction, but could not touch the foreign body. This proceeding caused urgent dyspnœa.

Soon after, the patient was seized with one of the worst epileptic fits which I ever witnessed. His face became almost black, and his features were hideously distorted. The air passed freely through the artificial opening during the fit, as evidenced by holding a lighted candle to the wound. The flame was blown out three times in succession. We dashed his face with cold water, and I raised with a hook the opening in the trachea, and kept it raised on a level with the wound. The mucus was carefully removed with a small sponge and feathers. The fit lasted about a quarter of an hour, and we feared that he would have expired in it. He recovered, and I again attempted to find the foreign body. On introducing the end of the little finger, I touched a hard substance lying at the left side of the larynx, close above the wound. I tried to seize it in a polypus forceps, but it slipped upwards towards the mouth. I then caught, and was enabled to remove, the set of artificial teeth, as represented in the accompanying woodcut. The patient was shortly afterwards seized with another epileptic fit, in which he soon expired.



The annals of Surgery afford numerous instances in which foreign bodies, of various forms and size, have accidentally entered the air-passages, amongst the most remarkable of which are the case of Brunel, the celebrated engineer, into whose larynx a half-sovereign slipped, and which, by a combination of artistic and scientific skill, was happily expelled thirty days after the accident—tracheotomy having been performed by Sir Benjamin Brodie; Houston's case, in which a large molar tooth entered and passed through the larynx during the operation of extraction; also cases of buttons, pease, fruit-stones, portions of bone, &c.; but, perhaps, the case now related has no parallel, in which so large a foreign body as seven artificial teeth, set in guttapercha, entered the larnyx and passed through the rima glottidis, and lodged at the junction of the larynx and trachea.

That a foreign body had entered the air-passage during a fit of epilepsy was evident in this case from the croupy breathing, urgent dyspnœa, and aphonia, corroborated by the fact that the artificial teeth belonging to the upper jaw were missed by the patient after the epileptic seizure, and could not be found. The stethoscopic signs were negative, in consequence of the foreign body having been fixed in the long axis of the trachea (as was afterwards ascertained in the removal of the teeth), and thereby not fully obstructing the entry of air into the lungs.

The necessity for bronchotomy was obvious, and was sanctioned on consultation with Mr. Porter. The danger of spasm of the glottis in this case was imminent and twofold, either from the foreign body being forcibly driven against the rima glottidis during expiratory efforts, or during a return of the epileptic seizure. I accordingly performed the operation of tracheotomy, ably assisted by Mr. Porter.

Such a procedure, at midnight, on an epileptic patient, having a fat neck, with enormous large veins, and a small and deeply-seated trachea, was a serious undertaking, and, so far as the operation itself was concerned, was perfectly successful. Death was obviously caused by prolonged and violent recurring epilepsy.

THE FOOD QUESTION.

By HENRY MAC CORMAC, M.D.

This question, its discussion and solution, comes, or ought to come, especially within the competence of medical men. I think it needs no insisting upon that the working-classes of these countries are not adequately nourished, thereby impairing or losing, so far as it depends on nourishment, the safeguard against disease of body and mind, which a sound habit of body ensures. The working-classes are adequately nourished nowhere. But many of the wealthy themselves, particularly women and children, and men who have much "head-work," as it is termed, are not at all sufficiently nourished, whether as regards quality or quantity. It is a great question, is the food question, and one that well-deserves patient care and attentive consideration. *In limine*, the appetite for and assimilation of food, largely depend on air, exercise, cleanliness, and variety. The art of cookery, irrespective of procuring proper sustenance of any kind, may, as regards the immense majority of the people of these lands, be well regarded as in next to a savage state. We do not devour our food raw, indeed, but the aid of art is very imperfectly called in. The cookery books are, one worse than the other, crude, ridiculous, and impracticable. There is a general *rationale* or principle of cookery which the authors of these treatises know nothing at all about, and which, nevertheless, should be prefatory to every treatise on cookery. The French have not arrived at the consummation or climax of the cooking art, nevertheless, they have arrived at a degree of empirical skill which, though somewhat exaggerated, is not the less perfectly surprising. If a French teacher of practical cookery were attached to every school, as well as a teacher of French, it would do a mint of good. I think Thomas à Kempis a wonderful book. I have read it several times, and hope to read it again. Nevertheless, Brillat Savarin would be productive of more *material* happiness at least. Dear Thomas was an ascetic of the first water, but Savarin was a cook in a very high sense, and certainly shows the importance of being well "done for" in the dining line. And, really, I do not see, I should like to know, what a man is good for that gets no dinner, or, at least, no adequate one. I have perused Soyer, Francatelli, and several other French treatises, but they are all, Jules Gouffé (which I have *not* as yet read), I fear inclusive, highly empirical, and no more calculated to teach cookery than treatises on the piano, or on swimming, alone, are calculated to teach swimming or playing on the piano. There must be practice. But practice, after all, is a poor thing without principles, and the cooks who write are hazy in the extreme on the subject of principles. They do not, in fact, Brillat Savarin, in a certain limited sense, excepted, know anything at all about principles.

Now, principles in cookery are like principles in everything else, the very lights and guides of the world. What we need are principles coupled with efficient practice; in fine, principles and practice, sound principles and sound practice. For the infant, the best food is, first, mothers milk, the healthy milk of a healthy mother. The next thing it needs, is the healthy milk of a healthy animal—say a healthy cow, or ass, or goat. Farinaceous matters and animal solids will come in due time. The various "foods" and "substitutes" are perfectly inadequate. Good cow, or goat, or asses milk, a little of the bruised yolk of a good egg, or a little good recent beef-tea, one or all, is the only approximately good substitute or substitutes that I know of, and one and all they are inferior, in its own time and place, to good mothers milk. For the mothers milk is prepared by the cunning hand of Nature, and for the creature it is designed for, is the best of all possible nourishments. And why is it so, simply because it is thus designed by the Maker of the infant. It contains, as to artificial "food," the azote, the carbon, the water, the sugar, the fat, the casein or fibrin, the phosphates, the carbonates and the sulphates, the iron, the lime, and, in fine, the various matters needful to build up the infant, wholesomely, blood and bone. Now, the mans food, *mutatis mutandis*, is the childs food. He must have the same ingredients, so wondrously combined in the mothers milk, that the babe has, agreeably, sufficingly, and variously served up to him. If any ingredient be absent or bad, or insufficient, he is sure to suffer, and in effect does suffer, grievously. The whole art of cookery, then, is to procure these diverse food ingredients, and to present them in an agreeable and sufficing form to the palate of the human being that is to make use of them. In the first place, the water must be pure. It must not be loaded with foreign matters or with living organisms. The food should be varied. Though milk no longer prove the exclusive sustenance, good milk, variously prepared, is an excellent ingredient of adult regimen. Wines, spirits, ales, tea, coffee, chocolate, each and all of them good of their kind, and in the guarded measure which sound sense dictates, have their uses. Bread comes next, good bread, to good water. Bread, too, should be varied, well prepared, and well cooked. Rice, barley, rye, wheat, Indian corn, with some foreign grains, separately or mixed, constitute the desirable ingredients. The grains, also, may be prepared whole. In the form of bread, the grains should be good of their kind, well mixed, well baked, carefully and cleanly manipulated. Wheat has the singular peculiarity that the inner or internal husk may be ground up, and incorporated with the bread. The advantages are great. There is a surplus of nitrogen gained, then there are the extra phosphates. Lastly, the bran particles obviate the constipation or costiveness which white bread promotes, and which proves in various ways so frequent a source of injury and distress. Whole meal bread, well baked and prepared, will sustain life alone, white wheaten bread will do nothing of the kind. Working men and women suffer very much from the bad white bread which they now so exclusively use, and which is really inadequate to the wants of the living organism. Some, however, very superfluously, I think, object to the bran particles. They say they irritate the bowels. Admitting that, as thus, the bran particles are objectionable, at least, in some persons, wheat has recently been ground down by the Messrs. Chapman into a perfectly smooth and homogeneous flour, by which all the nutritive properties of the bran are retained, while the roughness and grittiness appertaining to the bran in ordinary are entirely obviated. *Probatum est.*

As we are constituted, animal food, fish, flesh, fowl, variously and agreeably prepared, seems, if not absolutely, at least approximately, requisite. It is to the preparation of these, variously combined with pulse, vegetables, and fruit, that the art of cookery is considered more especially to apply. In fact, the animal foods, as prepared, and coupled with those derived from the vegetable worlds, mineral and vegetable condiments inclusive, *must* contain the ingredients of which mothers milk or the egg yolk is the so perfect standard. If they do *not* contain these ingredients, the animal frame perishes or becomes inadequate to the performance of the various requirements of this life. The cook would need to be something of a physician, the physician somewhat of a cook. Into the preparation of foods, it is here out of the question to go. I have, at least, signalised some of, nay, the leading *principles* which the consideration of the preparation of food should comprise. Milk, water, bread, animal fibre, along with wines, fruits, and vegetables, constitute the food of man, a varied bill of fare truly. There is, however, one dish to which I must advert ere I have done, as it much concerns the welfare of working-men, and all men, in fact, are, or at least ought to be, working-men. That is the Stew. With good bread, good water, good milk, good wine, good fruit, grains, pulse, and vegetables, and a *good stew*, any man might live, and live well. And, really, I do not think that any human being should have a more restricted fare. Every working man and working woman should, at least, have this. If I could have my will, I would have the Legislature or, at least, some public body, to offer a thousand pound prize, with approximately smaller prizes, to him or to them who should devise the best stew or stews. And having devised such stew or stews, I would have the process taught in every family and in every school. It would prove a more important problem, solved, than the philosophers stone, even the solution of the north-west passage, or the finding of the longitude. With a good stew, daily, and the other ingredients I have mentioned, disease of body and mind and material unfitness, generally, would have received a sore blow and great discouragement. The "Irish stew," the Spanish "*olla*," the French "*pot-au-feu*," and "*bouillibaisse*," or fish stew, and the "Indian curry," are all approximately good dishes. And there might, perhaps, be something better. Some years since I published a receipt for a stew. Hopefully, some one else will do yet better, and a very great good might thus be effectively and finally consummated.

UREA AND URIC ACID: THEIR RELATION TO HEALTH AND DISEASE.

By B. KELLY, M.D., L.K.Q.C.P.I.

(Continued from page 74.)

Considerable controversy has long existed, and still exists, respecting the topical formation of carbonate of ammonia in albuminuria. Frerichs is of opinion that this substance is always generated in the circulation, from the decomposition of urea, and not in the stomach and intestines, as Barreswil, Bernard, and other physiologists maintain. But, apart from the high authorities opposed to the theory of Frerichs, there are many considerations which militate against the correctness of his views. In the first place, I cannot well understand why ammonia should be so readily formed in the blood of uræmic patients from the decomposition of urea, when we know the latter substance constantly exists in greater or less quantity in the blood during health, without giving rise to a similar metamorphosis. Were Frerichs' theory, moreover, perfectly sound, albuminuria would cease to be the formidable and fatal disease it really is, for all the urea generated in the system would be gradually changed into carbonate of ammonia, and be steadily eliminated by exhalation from the lungs. This is the usual manner in which this agent is removed from the economy, when injected into the veins; and the same, doubtless, would ensue in albuminous nephritis. When, however, the urea accumulates to such a degree as to require to be excreted by the gastro-intestinal mucous membrane, it becomes readily transformed into ammonia by contact with altered mucus and other vitiated secretions which abound, under such circumstances, in the stomach and bowels. The new-formed carbonate is then capable of being absorbed, precisely in the same way, and with similar effects, as when given as a medicine by the mouth; so that its presence in the blood in cases of uræmia is by no means conclusive evidence that it had originally been formed in the vascular system.

As to the nervous accidents—amaurosis, deafness, convulsions, &c.—which are said to depend upon the existence of ammonia in uræmic blood; there is good reason, on the contrary, to suppose that these symptoms arise rather from the loss of albumen, coupled with an excess of retained urea in the system, and the consequent escape of the serum into the connective tissue of the body. Ammonia has been injected in large doses, by way of experiment, into the jugular veins of healthy animals, without producing any graver accidents than acute pain and jactitation, which, however, soon subsided. Even in the cases cited by Frerichs in corroboration of the former theory, in which convulsions, stupor, &c., followed the introduction of carbonate of ammonia into the vascular system, the animals speedily recovered the shock, and soon regained their usual health and vigour. The escape of the serum, consequent upon the abundant excretion of albumen by the kidneys, is virtually tantamount to one or more copious general bleedings, for the blood becomes thereby depleted of two most essential constituents, not to speak of numerous saline substances scarcely less important. The mere presence of the serum in the meshes of the areolar tissue, or in the cavities of the chest and abdomen, is of no more avail to the healthy nutritive functions than if it were totally eliminated from the body. And as the blood in such cases has lost its plasticity and endosmotic power in a great measure, it remains permanently altered in quality, and deficient in normal proportion. Bleeding, we know, when carried to excess, will produce all the symptoms following in the train of albuminuria—amaurosis, deafness, convulsions, coma, and death.

In gout and rheumatism there is a remarkable disparity in the final disposition of the uric acid and urates, so abundantly generated in both these diseases. In the former the acid, with its compounds, exhibits a peculiar tendency to collect, in the form of tophaceous concretions, in and around the diseased joints, as though these parts were the laboratories in which they had been fabricated, while only a comparatively small portion of them is eliminated by the kidneys. In rheumatism, on the contrary, the articulations never become the seat of similar deposits, it matters not however long the disease may have continued, or how swollen and painful have become the joints; whereas the sweat and urine point to the proper emunctories, and bear ample testimony to the free removal of the morbid products from the system.

The acidity of the urine, as it appears, does not depend upon the amount of uric acid and urates, but rather upon the quantity of acid phosphate of soda held in solution in this liquid. Liebig, after emphatically enunciating this fact, advances a step farther, and states that as lactic and acetic acids are rapidly formed in the urine after its excretion, its acidity, therefore, does not always depend upon the acid phosphate of soda alone, but also upon free *hippuric* and lactic acids. It is not necessary, however, that urine should contain grape sugar in order that lactic and acetic acids be produced by fermentation—their presence in this liquid being sometimes traceable to the decomposition of an azotized extractive matter in union with a substance resembling dextrine, if not in physical, at least in chemical characters. Furthermore, when the perspiration, which also contains free lactic and acetic acids, is suddenly checked by cold, or by inflammatory action, these substances are thrown back upon the blood, and are eliminated by the kidneys. Then, again, the amount of carbonic acid, dissolved or suspended in the urine, is sometimes so considerable as to give it a decided acid reaction, and it generally exists in sufficient quantity to keep the phosphates, even when abundantly excreted, soluble in this fluid. After micturition, however, the greater portion of the acid escapes, owing to its volatility, when the phosphates become precipitated in the form of a whitish, flocculent deposit. Upon the application of heat, the carbonic acid is more thoroughly expelled, and hence we often see a copious sediment of earthy phosphates produced, which, in the absence of the nitric acid test, is so liable to be confounded with albumen. These facts sufficiently account for the urine containing these salts being acid on emission, but soon after becoming neutral or alkaline, without having recourse to the more complex mode of explanation deduced from the development of ammonia by the action of putrid mucus upon urea, and the consequent precipitation of the neutral or acid phosphates.

Dr. Bence Jones, lecturing on the urine, says—"If the degree of acidity is slight, a large quantity of urate of ammonia may remain in solution; if the acidity is considerable, then even a small quantity of urates may give a precipitate." The thicker and more turbid the urine in such cases, the more acid, generally, will be its reaction, and *vice versa*. From this we may reasonably infer that urate of ammonia and other urates, whether they exist in small or large quantity, are precipitated by a highly-acid urine; whereas a sparingly acid, neutral, or alkaline liquid is favourable to their solution. The knowledge of these facts is most important, for by it we not only get a clue to the formation of urate of ammonia and uric-acid calculi, but also to their most rational and efficacious treatment. It may be mentioned in connection with this subject, that Heller attributes the acidity of the urine, so common in Bright's disease, not to the presence of uric and hippuric acids (for these substances are not always constant), but to uroxanthin.

Before concluding, I purpose saying a few words upon the oxalic diathesis, and its relation to urea, uric acid, and urates in the urine.

Great uncertainty still exists respecting the formation of oxalic acid in the system. That it effects an entrance therein after the use of sorrel, rhubarb, tomatoes, and other edibles normally containing it, either in the free state or in the form of oxalates, there cannot be a reasonable doubt; but to account for its spontaneous generation, so to speak, in the living organism, is a problem very difficult to solve.

Liebig, Frerichs, and Wöhler have obtained three distinct products from boiling together uric acid and the peroxide of lead, namely—oxalic acid, urea, and allantoin. They also affirm that the same play of chemical affinities, attended by similar results, is capable of being performed in the interior of the body. Other experimenters, less fortunate in their attempts, have failed to corroborate the truth of this theory. M. Gallois has only once succeeded, and that in his own individual case, to detect oxalic acid in the urine after the ingestion of a soluble urate into his stomach. Oxalic acid may then be formed in the system by the oxydation of uric acid in contact with some agent like the peroxide of lead, capable of yielding up its surplus, or feebly-retained oxygen; but, inasmuch as the presence of one or both these organic substances, either in the free or combined state, is incompatible with the alkalinity of the blood, and the consequent decomposition of sugar into water and carbonic acid, the question inevitably rises—what becomes of the sugar that is constantly poured into the general circulation through the hepatic veins. It must either suffer decomposition or combustion, or be eliminated by the kidneys. But we know it cannot be destroyed in the blood unless the alkalies abound in sufficient quantity for that purpose; and I am not aware that oxaluria and diabetes are ever concomitant affections.

All the elements to which the nitrogenous constituents of the food and tissues of the body may be reduced by ultimate analysis are capable of being oxidized under certain favourable conditions, to their highest possible degree. Thus carbon, sulphur, and phosphorus, become converted in the system into carbonic, sulphuric, and phosphoric acids. Why may not nitrogen also be changed into nitric acid, by the synthetic power of animal chemistry? By once admitting the possibility of the formation of this acid in the economy, we could readily account afterwards for the production of oxalic acid and oxalates in the system, and for the simultaneous absence of sugar in the urine, when otherwise we should reasonably expect to find it in that liquid.

The fact that oxalate of lime is found much more abundantly in the urine after a copious meal, than in that passed in the morning, would seem to lend additional force to the hypothesis that oxalic acid is formed in the blood from the oxydation of hepatic sugar; for were it to originate from imperfectly assimilated food, or from disintegration of the elements of the tissues, the so-called *urina sanguinis* would, doubtless, contain the largest proportion of it. That the oxydising agent is nitric acid, or one of the same chemical series, is rendered probable when we reflect that free nitrous acid has been detected in the urine after the administration of the urate and other salts of ammonia, and, as the condition of system generally accompanying oxaluria, is also that in which the urate of ammonia is found in greatest quantity, and as this substance decreases, *pari passu*, with the diminution of the oxalate of lime in the urine, the proofs in favour of the hypothesis advanced become the more cogent and convincing.

According to Lehmann, oxalic acid and the oxalates are formed in the system, through the agency of the alkaline carbonates, vegetable salts, and carbonic acid, contained in many articles of food and drink, aided by certain conditions which morbidly affect the respiration. He considers, moreover, that the excessive amount of carbonic acid thus introduced from without, as well as generated in the body by the substances alluded to, prevents the absorption of oxygen, and the consequent oxydation of certain principles (which, however, he does not specify) existing in the blood; and, hence, he concludes the increase of oxalic acid in the urine. In proof of the hypothetical soundness of this theory, he cites the examples of emphysema and pregnancy, in which the oxalate of lime is occasionally found to exist in the urine as an adventitious product.

As to the formation of oxalic acid being due to a deficient oxydation, I would merely state that this assumption is opposed to the views of most other chemists, who trace its origin to an oxydation of uric acid. An alkaline condition of the blood, moreover, is unfavourable to its development. As to the presence of oxalate of lime in the urine of pregnant women (which Lehmann attributes to impaired respiration, from pressure of the gravid uterus), I deem it, at best, a mere coincidence; or it may possibly result, in such circumstances, from the death and decomposition of spermatozoa. Wolff, of Bonn, Donné, and more recently Bence Jones, and Ch. Robin, have drawn the attention of physicians to the somewhat novel but important fact, that oxaluria is a very common collateral complication in persons afflicted with spermatorrhœa. Indeed the latter goes so far as to declare in his lectures that the existence of the characteristic octahedral crystals in the urine is not only a concomitant, but even a pathognomonic, symptom of this affection. But whether oxalic acid results in such cases from the decomposition of the semen, or is generated in the system by reason of a special cachectic modification of the nutritive functions, induced by the loss of so vital a fluid, is very difficult to determine in the present state of medical science. Dr. Walshe has observed that the quantity of oxalic acid and its compounds is often increased in the urine during convalescence from typhus, rheumatism, and many other acute and chronic diseases in which the process of digestion had been seriously deranged. For my own part, I am strongly disposed to believe that the dyspeptic symptoms, the lassitude, debility, palpitations, and the whole train of nervous phenomena, so commonly met with in cases of oxaluria, are neither an effect nor a cause of that ailment, but are to be traced directly to the profound impression made upon the system in general, by the long continued loss of sperm, whether that waste had been induced by a voluntary act, as in masturbation, or by an involuntary sexual erethism, as in nocturnal emissions.

Dr. Schmidt, of Dorpat, altogether denies the possibility of oxalate of lime traversing the epithelial cells of the kidneys, and, therefore, has recourse to an ingenious explanation to account for its presence in the urine. According to him, the acid urine contained in the bladder and renal ducts, decomposes the soluble oxalate of albumen lime secreted by the mucous membrane of the parts, thereby disassociating the albumen, and precipitating the insoluble oxalate. In the same manner, he says, oxalate of lime is formed from the mucous secretion of the gall-bladder.

The assertion that oxalate of lime, as such, cannot overstep the barrier offered to its passage by the renal epithelium, seems opposed to the views of other competent and candid observers. Garrod has detected crystals of the oxalate of lime in the blood; and Golding Bird, while acknowledging the absolute insolubility of this substance in water, emphatically pronounces its solution in the urine, from the fact of its crystals presenting a transparent, lustrous form. He adds, moreover, that the epithelial cells have been found distended with the crystals of oxalate and uric acid in certain urinary deposits. According to Kölliker, on the contrary, the concretions of urates and calcareous salts, which accumulate so often in the uriniferous tubes of vertebrate animals, have not been demonstrated, as yet, with certainty in the renal epithelial cells. The mere fact of Dr. Garrod's having found oxalate of lime in the vascular system, does not prove, by any means, conclusively, that it subsequently makes its way through the kidneys into the urine. It would be quite sufficient, [illegible] to me, in view of the hypothesis already advanced, to recognise the formation of oxalic acid in the blood, and its immediate conversion or not, into a soluble potash or ammonio-salt, to account for its existence as an oxalate of lime in the bladder, seeing that calcareous matter is so abundantly met with on certain mucous surfaces, and more especially on those of the urinary organs.

The arguments of Professor Lehmann on this subject, are worthy of serious consideration. "That oxalate of lime," he says, "is at first actually held in solution in filtered urine, and that it does not, as C. Schmidt supposes, proceed from the mucus of the bladder, is a view which is supported by the experiment which I have often repeated, that in urine, which, after thoroughly cooling and freed from its mucus and urate of soda by filtration, the most distinct crystals of oxalate of lime might, after a time, be recognised, while no traces of them could either previously be detected in the mucus of the fresh urine, or found after the residue on the filter had been for some time in contact with water. The oxalate of lime," he further adds, "does not separate from filtered urine until after it has stood for some time." We thus see that the seductive theory of Schmidt respecting the formation of the product in question, from the decomposition of oxalate of albumen-lime by acid urine, is gravely controverted, if not completely refuted, by the result of the foregoing experiment.

In oxaluria the urine always presents a more or less marked acid-reaction, which is not so much due to the excess of oxalates, and acid urates, and phosphates contained in it, as to the presence of free uric acid. The proportion of urea found in such cases, varies widely from the normal standard, being sometimes more, sometimes less, than the quantity usually excreted in health. Its amount, however, generally bears a fixed relation to the number and size of the oxalate of lime crystals. Hence the density of the urine ranges from 1010 as high as 1030, and even 1040. The specific gravity, therefore, of oxalic urine is no criterion whereby to diagnosticate this serious affection, the only safe and reliable means for that end being the microscope and chemical analysis, taken in connection with the general condition of the patient.

A TWO MONTHS' SUMMARY OF CASES TREATED AT THE WESTMORELAND LOCK HOSPITAL.

By Mr. MORGAN,

SURGEON TO THE HOSPITAL, PROFESSOR OF SURGICAL AND DESCRIPTIVE ANATOMY R.C.S.I., AND SURGEON TO MERCER'S HOSPITAL.

During the last two months several cases of interest have been under treatment, as will be seen by referring to the tabulation given. Some allowance must be made for inaccuracy in history, considering the class concerned, but considerable pains have been taken to arrive at the nearest approach to a true record of the condition and previous history as to disease of each; the classification I have adopted will briefly afford some details of the phases and variations in succession which occur.

Five cases of chronic indurated sores have been under treatment, all presenting the same character of impassiveness, density, smooth surface, with little or no discharge, comparative insensibility to the application of escharotics, four of them being of considerable extent, varying in size from upwards of a crown-piece to a florin, auto-inoculation was tried on several occasions with negative results. From the insensibility and chronic nature of these sores, the patients endured them for a considerable time before seeking admission. One of these cases was treated in the hospital for this same sore eleven months previously, she left the hospital and pursued her mode of life for three and a-half months before seeking re-admission, all the time, without doubt, having this sore in existence, and in *statu quo*. Nearly five months ago the patient was re-admitted, having, in addition to the sore, a papulo-squamous eruption in clusters over the body, and no other constitutional sign but hardened inguinal glands on both sides.

The other examples of this sore are of 5, 7, 14, and 15 months' duration. In all there was hardening of the inguinal glands, and in one case a slowly suppurating dense bubo formed.

An intra-vaginal and uterine form of this sore was found in one case; the only *external* manifestation being hardened inguinal glands on both sides, and alopæcia.

Amongst the cases affected by primary sores for *the first time*, there have been ten of soft sores, three of which have already presented decided constitutional symptoms.

No case of indurated sore or with accompanying density of the inguinal glands was seen amongst those admitted as general patients who had been previously affected on one or more occasions, while there have been twenty-four instances of soft sore with or without constitutional symptoms, which, in some cases, were apparently due to the original infection, in others to the existing.

Phagedænic ulceration existed in three cases to an immense extent, from sixteen to ten months being occupied in repair. In one case, the urethra was destroyed up to its vesical termination. In others, an extensive sheet of ulceration was left, extending over the nates, &c. All the sufferers appear to have sought admission directly after being affected by the sore, which, from the first, showed a phagedænic tendency.

Two married women in the early stage of pregnancy have been under treatment, and two syphilitic children, whose mothers presented no sign of original or present taint.

GENERAL PATIENTS, HAVING BEEN PREVIOUSLY IN HOSPITAL.

Disease.	How often Diseased before.	At what Antecedent Periods.	What Constitutional Symptoms.	Observations.
Extensive soft sores	1	6 years	None	Hypertrophied labium and nympha, operated on and removed
Soft sore and vegetations	1	14 months	None	Had bubo with first sore
Soft	1	18 months	Papular eruption	
Soft	1 1	2 years 1 year	Severe joint pains	
Soft	1	3 years	None;	
Soft	1	6 months	None	With gonorrhœa and aphthæ uteri
Soft	0	6 weeks	Mucous patches and papular	Has gonorrhœa 18 months' duration
Soft	1	4 years	Papular	Had gonorrhœa 2 years ago
Soft	1	3 years	Papular and acne facei	Had gonorrhœa 18 months ago. Several fistulæ in ano. Operated on
Soft hypertrophied labia	1	8 years	None	Immense vegetations. Hypertrophied labia. Operated on
Several soft	1	18 months	Buboes suppurating	
Soft (extensive)	1 1	1 year 8 months	Severe pains	Hypertrophy of nympha. Operated on
Soft (several)	1	6 months	None	
Soft	1	3 years	None	Gonorrhœa six months ago
Several soft	1 1	1 year 8 months	Abundant papular eruption	
Several soft	1	4 months	None	
Large soft	4	In two years	None	Gonorrhœa five months since
Several soft	0	0	None	
Large soft	1	7½ years	None	
Soft	1	7 weeks	None	Twins, dead born, 4 weeks before admission. Primary existing at the time.
Soft (large)	1 1	3 years 6 months	Alopæcia only	Had gonorrhœa 12 months ago
Soft (several)	0	0	None	Had gonorrhœa 5 months since
Soft (large)	1	2 months	None	

PHAGEDÆNIC SORES.

Phagedænic—14 months, recovery	1 1	2 years with bubo 1 year with bubo	Gummata, exfoliations, nodes	Urethra destroyed. Operated on—plastic operation
Phagedænic—10 months, recovery	1	11 months	None	Most extensive over sacrum, &c.
Phagedænic—16 months, recovery	1	16 months	None	Most extensive over nates and sacrum
Phagedænic—not extensive	1 1	17 years 1 year	None	Had 8 healthy children

INDURATED SORES.

Extensive and chronic—11 months' standing	1	3 years	Papulo-squamous, pemphigus, syphiliticus	Not auto-inoculable
Extensive and chronic—7 months' duration	1	13 years	None, hard inguinal glands	Not auto-inoculable
Extensive hard—15 months			None, ulcerated rectum, hypertrophied labia	Not auto-inoculable; labium operated on and removed.
Small hard—5 months	1	8 years	None, hard, slowly suppurating bubo, iritis	Not tried
Hard on uterus and posterior wall of vagina—9 weeks' duration	0	0	Alopæcia, very hard inguinal glands	Not auto-inoculable
Chronic sore, extensive—14 months' duration	0	0	Extensive ulceration of urethra—No constitutional signs	Not auto-inoculable

1ST ADMISSIONS, NOT BEFORE DISEASED.

External Disease.	Constitutional Symptoms.	Duration.	Observations.
3 Soft	Roseolar, ulcer tonsil	2 months	Cachectic.
2 External soft 1 Intra-vaginal	None	5 weeks	
2 Soft	Abundant papular and pityritic	3 months	
3 Soft	None	3 weeks	Had gonorrhœa 3 months since.
Large vegetations	None	6 months	No primary observed.
1 Soft	None	2 months	Seven months; child since born, lived 24 hours; not syphilitic; has intra-vaginal growths.
1 Large soft	None	3 months	
Several soft	None	5 weeks	Non-suppurating bubo.
1 Soft	None	1 month	
Several soft	Cachectic, papular	3 months	Laryngeal ulcer at chorda-vocalis.
Large soft	None	2 months	None.
Large soft	None	1 month	None.

GONORRHŒA.

Disease.	No. of times affected.	At what Antecedent times.	Observations.
Gonorrhœa	4		No complications.
Do.	1 1	18 months ago 9 months ago	Has abscess of labium.
Do.	1 1 1	2 years 18 months 2 months	No complications.
Do.	1	5 months	Ovarian irritation.
Do.	1	6 months	Profuse discharge, and apthæ uteri
Do.	1 (sore and bubo).	8 years	Debilitated and purpuric.
Do.	1	1 year	Large abscess posteriorly.
Do.	1	5 months	Ovarian irritation and tumefaction.

CONSTITUTIONAL SYMPTOMS ONLY.

Primary Disease.	How often Diseased.	At what Antecedent Dates.	Observations.
None	1 1	2 years 18 months	Large vegetations
None	1 1	5 years 1 year	Pains cachexia, threatened phthisis
None	1	5 years	Slight pains ; exfoliations of cranium
None	1	1 year	Severe papular and ulcer tonsil
None	1	4 months	Mucous patches and papular
None	1	2 years	Deep coloured maculæ, pains, hard inguinal glands, ulcerated lip
None	1	8 months	Rupia and ulcers
None	1	4 years	None; ulcerated larynx, epiglottis ulcerated very considerably, ulcer of eyelid
None	1	18 months	Roseola and papular, no pains

MARRIED WOMEN AND CHILDREN.

Character of Present Disease.	Previous Disease.	Constitutional Symptoms.	Duration.	Observations.
1 Several soft sores	None	Roseola	6 weeks	4 months pregnant (first time).
2 Several soft	None	Mucous patches	6 weeks	Has had healthy children, the last 1 year old
3 No primary	None	Vegetations	2 months	Pregnant first time, 4 months
4 Ulcer soft, palate perforating	6 years	None	5 months	Has a healthy child 6 months old in arms, and three living
5 Discharge leucorrhœal	None	None	10 months	Slight prolapse of uterus
6 None	None	Copious papular, severe pains	2 months	Infected by pregnancy; had miscarriage 7 months

CHILDREN.

One, six weeks old, very weak and despaired of, covered with papules making good recovery with mercurial treatment.

One, seven weeks, abundant papula, but a strong child, making a good recovery with mercurial treatment.

CASES OCCURRING IN THE PRACTICE OF

J. MARTIN, F.R.C.S.I., L.K.Q.C.P.I.

Mary Byrne, æt. 49, had a large tumour of eleven years' growth, of an oblong shape, about twelve by five inches, and running from the upper edge of the left scapula, along its posterior edge. The weight being inconvenient, and the size of it interfering with her comfortably lying in bed, she desired to have it removed. This I did by two elliptical incisions; two small vessels required ligature ; the edges of the wound, 13 inches in length, were brought together by iron wire sutures ; nine-tenths of the wound were healed by first intention, and at the end of ten days she returned home, a spot about the size of a sixpence being unhealed. The tumour weighed, after removal, 3 lbs. 12 ozs., pure adipose, with intersecting fibrous bands.

Mrs. S. B., æt. 65 years, had a tumour on the back of the left thigh, immediately above the upper angle of the popliteal space for 17 years, which she concealed, until ulcerating about two years ago, it became so painful that she wished its removal. The base being circular, and the integument over the tumour in an unhealthy state, I removed it by two elliptical incisions, the sides of which, however, could not be brought into apposition. No vessel required ligature. The wound healed by granulation with singular rapidity. The mass, when removed, weighed 18 ozs. of fine white adipose.

Mary Green, Killcommon, æt. 27 years, while pregnant of her second child, was attacked with a growth of epulis on the gums of the first and second molar teeth, lower jaw, left side. Having nursed for nine months, her health being much impaired, she consulted me ; the epulis then being about the size of a large walnut. I made her wean the child, and put her on a course of chalybeate tonics. Two months after I removed both teeth, and cut down, with a saw constructed for the purpose, on each side of the epulis, then removed the intermediate parts with a cutting pliers. It healed quickly, and now, after 18 months, has not returned.

This operation was performed two years ago. Since I sent the above to press I have heard that she has had another baby, has nursed it for four months, and that during the past three weeks the hypertrophy of the gums has set in again, and slight enlargement at the seat of the former epulis.

Mrs. Brennan, æt. 28 years, Co. Kilkenny, consulted me for an epulis, about the size of a hazel nut, on the gum, under the right canine and first bicusped teeth, lower jaw, both were loosened from their attachments, there being a general hypertrophy of the gums. She was rather debilitated from nursing during the previous 9 months. I made her wean the child, and put her on a course of iron and quinine. I then extracted the teeth, cut down with Hey's saw on each side of the epulis, and removed it with a cutting pliers. It healed quickly, and under the use of iod. potass, liquor arsenialis, and iod. ferri., the gums resumed their natural state, and she recovered perfectly.

This operation was performed two years ago, and the patient has remained quite well until very lately. Since I sent the foregoing for publication I have heard that she had another baby about three months ago, and nurses it, and that during the past three weeks some slight enlargement has shown itself in the old seat of the disease, and that all the gums show hypertrophy.

It is remarkable, both these cases having occurred during the cachexia produced by nursing.

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION : THEIR DIAGNOSIS AND TREATMENT.

By S. Scott Alison, M.D. Edin.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

No. III.

The symptoms which enable such conditions of the throat to simulate tubercle of the lungs are many, and the physical signs are not very few which give rise to the same result.

Cough is one of the symptoms which is calculated to deceive in the diagnosis. This is almost always present, and is generally frequent, occurring in the morning, and repeating throughout the day. Sometimes it occurs at night, but this is comparatively seldom, and the patient may sleep many hours uninterruptedly. The cough in its character is generally short and dry, and is rarely marked with long, violent, and repeated expulsions of air from the chest. The cough-sound sometimes resembles a subdued hissing issuing from the glottis; sometimes the sound is an abrupt explosion one, single, or at least distinctly divided. The sound also combines, in many cases, a ringing, metallic-tube character. Sometimes the cough assumes a decided loud, snappish, dog-barking character. In cases of morbid narrowing of the trachea, the cough assumes a constrictive sound distinctly traceable to the trachea.

"Hemming" is a frequent attendant of simulating throat affections. In some cases the local voluntary muscular effort which produces this noise is almost unceasing. From early morning till the moment of sleep it is to be heard, and while it seems to afford only a little relief to the patient, or serves to bring up only a very small amount of mucus from the larynx and the lower part of the pharynx, it succeeds in causing great and wearing-out annoyance to those placed about the patient. In most cases this "hemming" is comparatively faint, but in some others it assumes a very harsh character, and may more properly be called "hawing," from the similarity of the sound of the muscular effort to the coarse sound of this word when pronounced in the ordinary or coarse, prolonged manner. This variety of hemming is almost intolerable to the ear at all raised above that of the ordinary savage.

Sneezing, which I find is a rare accompaniment of pulmonary consumption, is not an infrequent attendant upon throat disease, simulating the more grave affection of the lungs

Sputum.—Sputum to some amount marks the throat affection simulating pulmonary consumption. Generally the sputum is moderate in quantity. It is brought up with difficulty for the most part. Judged of by the patient's feelings, it appears to come from the glottis, the larynx or trachea, or from the posterior part of the mouth—*i.e.*, the pharynx. In ocular appearance it is often mere thickish froth, with minute air-vesicles, and white in colour. Very often the sputum, still scanty, is formed, so to speak, of so many lobules, coherent, somewhat transparent, destitute of air-vesicles, and having small points of black material studded throughout, the general aspect being that of washerwoman's prepared starch, but presenting a certain nodulated appearance. It may be said also to resemble prepared or boiled sago. This sputum is the secretion of the glands situated in the trachea, and at the bifurcation of that tube. The black particles are not composed merely of soot and other extraneous bodies deposited from the inhaled atmosphere, but is in part an organic production—a carbonaceous corpuscle, much larger than the mucus one, well worthy to be submitted to the microscope by the student.

In some cases the sputum is pretty copious, and consists of mucus of a gelatinous or glutinous character, having only very few air-vesicles. The colour is usually faint yellow, or green. This is expectorated with a full, easy cough. The tubercle corpuscle and the elastic curly lung fibre of course are absent.

Hæmoptysis, though a form of sputum, is usually treated of separately. For the most part, in throat disease simulating pulmonary consumption, the hæmoptysis is slight, and appears continuously for some days to intermit and then to appear again. It seldom comes on without coughing or hemming exertions. It is usually scanty, appearing in quantities sometimes amounting to a drachm, of a florid colour, and in a liquid form. Generally the blood is of a bright arterial colour, and simply tinges frothy mucus, or streaks yellow or green mucus. In some cases of throat affection simulating tubercle of the lung which have been treated by me in the hospital, blood has been expectorated to the extent of an ounce or two in that institution, and under close inspection; and in some of the cases, more especially of young women in whom the catamenia had been irregular, it has been stated that, on one or more occasions several ounces of blood have been expectorated. In the case of some young men with highly congested fauces the same thing has been related.

The discharge of blood from the throat and adjacent parts has generally taken place at the time of coughing; but in some examples the blood has come without any respiratory effort, and this, too, takes place chiefly in the morning, on awaking. The blood is generally arterial, but I have seen it dark and coagulated. When dark and coagulated inspection of the fauces has not unfrequently detected dark clots adhering to the posterior wall of the pharynx, and the mucus membrane itself in a highly roughened and congested state.

The blood issues from various parts; in most cases it proceeds from the highly injected mucous membrane of the trachea, often, I believe, near its bifurcation. I have frequently heard fine crepitation over the trachea in such cases. The tonsils are sometimes the seat of the discharge. More frequently the blood comes from the pharynx. In such cases the blood may sometimes be observed *in situ*. I have, at the present moment (Feb. 4), a young woman in the hospital, affected with chronic hemiplegia, suffering from throat disorder simulating phthisis, on the posterior wall of whose pharynx I observed, on the first examination, a large clot of black blood resembling a fungous growth. This was got rid of in a day or two. The patient had been sent to the hospital under the impression that she was suffering from lung disease, a certain amount of emaciation, cough, and general debility, leading to this idea. No evidence whatever of departure from the healthy condition of the chest signs was procurable, in this case, excepting a moderate amount of harsh respiration at the apex of the lung, and a certain amount of unduly prolonged expiration in that quarter, all due to disorder of the trachea and adjoining parts.

The discharge of blood in many cases is greatly promoted by a morbid state of the circulating mass.

The Voice.—The voice has been generally affected in the class of cases under consideration, but this has usually been to a moderate extent. In a few cases, however, the change in the voice has been very great. Sometimes the change in the voice has been only occasional, but in some, and in the more grave examples, it has been almost permanent.

The conditions of the voice most frequently noticed in these cases are weakness, huskiness, indistinctness, continuous hoarseness and discordance. There may be almost total loss of it.

The weak voice is often connected with mere congestion of the trachea and larynx, some tumefaction and dryness of the parts. The *loss* of voice is generally mixed up with œdema of the glottis, paralysis of the muscles and ulceration.

A total but temporary loss of voice is liable to occur in the case of females, when they have been exposed to mental excitement, and this condition is occasionally remarked under mere moderate changes of temperature, and moisture of the atmosphere, and under the influence of moral causes. I have now in the Rose Ward (May, 1868), a young woman sent to the hospital for chest disease, who has no appreciable disease there, whose voice is scarcely audible, and this depends merely on a dry condition of the larynx and glottis, and some temporary debility of the muscles of the larynx. The laryngoscope shows no organic alteration. Galvanism has been employed but without any beneficial result.

The general health in the cases of disorder of the trachea and adjacent parts which simulate pulmonary consumption is generally disturbed, and this disturbance is one of the chief reasons for the entertainment of the opinion that tubercle of the lung is present. The chief forms of disturbed health with which I have met, are the following :—

Emaciation.—Emaciation is generally present and to some material extent. In some cases the patient is merely rather thinner than before, but in others the loss of flesh is marked ; the roundness of the body is lost, and is replaced by obvious angularity and stringiness. It is this loss of flesh, conjoined with cough, which first suggests to the relatives and friends of the sufferer the suspicion of consumption, and it is this which causes the medical attendant to fear the presence of tubercle in the lung. In most, but by no means all, the examples of disorder of the trachea and other parts of the air-tube apparatus, which have seriously simulated consumption of the lungs, this loss of flesh has been present. It is right, however, to say that cases of simulated tubercle of the lungs have come into the hospital in which not only no emaciation was observable, but cases have been admitted from time to time in which the patient was not only in fine condition, but in respect of muscle and fat above the average.

The loss of flesh in such cases is less remarkable than the almost sudden regaining of it in the hospital. Very few of the patients have remained above a very short time under treatment without gaining a great increase of weight. Two or three pounds in weight have been gained in the course of a week or two by young females. As much as a stone in weight has been the increase in the course of two months. It was only a few days back that a young girl, sent in as consumptive, affected only with tracheal congestion, marked by cough, huskiness of voice, and some loss of flesh, was found to have acquired no less than 17 lbs. This great increase of weight forms a valuable piece of testimony in favour of the healthy condition of the lungs, and of the restriction of disease to the air-tube apparatus. But it is never to be forgotten that this testimony is not conclusive by itself, for I have known cases of tubercle of the lung, with cavity, to be marked by a very great increase of weight, as much as two stone in the course of a few weeks. The *permanency* of the increase of weight in disorders of the upper air-tube apparatus is worthy of note. The improved weight remains, but in cases of tubercular excavation it is otherwise in general. Within a week or two of leaving the hospital it is common for the tubercular patient to lose many pounds, and I have commonly noted, on the re-admission to the hospital of tubercular patients, who had gained much increase of weight, a remarkable and obvious emaciation and that the period of a year of comparative exposure, inferior diet, and non-attention to exhausting symptoms, had sufficed to cause a loss in weight of one or two stone, not now to be readily rectified for the second time, or at all to be replaced.

There is seldom present, in the class of cases under consideration, a material increase in the rate of respiration. But there is a difficulty of respiration both in the act of inspiration, and in that of expiration; and this is referred, without hesitation by the patient, to the throat. The act of inspiration is prolonged, and so is the expiration through the trachea. In tubercle of the lung the respiration is generally quickened.

The Circulating Organs.—The heart's action is seldom accelerated, and the pulse is usually of moderate rapidity, and is regular. In tubercle of the lung the pulse is usually quickened, and the heart more or less excited, except in chronic cases.

Digestive and Supplementary Organs.—In mere disorder of the trachea and adjoining parts, the digestive organs are seldom morbidly affected. The vomiting in early tubercle of the lung, and the persistent diarrhœa of the same disease in its latter stages, are seldom simulated, but these conditions are sometimes present.

The Skin.—The integument of the body in the simulating disorders, is generally healthy. There is no approach to the harsh and dry condition of the chronic form of tubercle of the lung in the wasted patient, nor to the moist, and soddened, and heated skin of the lung-tuberculated patient, suffering from the disease in its active form, and accompanied with irritative fever.

The hair, in examples of disease described above, simulating pulmonary consumption, seldom suffers, which is different from what is observed in phthisis, in which disease it is seldom long unaffected, becoming weak, and falling out to a great extent, especially in acute cases, to the great vexation of the patient, particularly the young female.

The temperature of the surface of the body, in the simulating disorders, is seldom heightened, and in this respect we note a difference in connection with tubercle of the lung, for in this disease the temperature is usually increased, as has been recently very fully established by many pains-taking physicians.

Generative Organs.—The disorders of the generative organs common in tubercle of the lung, are seldom noted in mere simulating complaints of the trachea. The catamenia are comparatively seldom suppressed, less frequently than they are in tubercle, and the debility of the male sex, common in tubercle, is also seldom or never observed in the minor disorders.

St. Pancras New Infirmary.—The Poor-law Board have given their sanction to the plans for the St. Pancras New Infirmary at Highgate, and have empowered the [illegible] to raise a loan of £40,000 for building the same.

Hospital Reports.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief notes by Dr. Tonge.)

Anæmia.—J. D., æt. 25, prostitute. Admitted March 1; discharged April 13. In hospital 43 days. *Much relieved.* Has drunk freely for last 2 years; very anæmic; basic systolic bruit over heart; occasional attacks of pain in chest. Never had rheumatism.

Iron, aperients, belladonna plaster.

Anæmia.—Frances F., æt. 16, bookfolder. Admitted May 24; discharged June 1. In hospital 9 days. *Very much relieved.* Previously ill, 14 days; faintness, palpitation, and dispnœa on exertion; pallor of skin and mucous membranes. Faint basic systolic bruit; tongue furred; appetite bad. Herpes zoster on right side.

Liq. ammon. acetatis, chloric ether, and liquor cinchonæ (7 days). Then quinine and iron.

Cephalalgia—Anæmia.—H. G., æt. 36, dairymaid. Admitted November 9; discharged November 10. In hospital 1 day. *Made out-patient.* Frontal headache, 3 years; pain in lumbar spine, 2 years; giddiness and shortness of breath on slight exertion; basic systolic bruit; sleeps badly; tongue furred.

Quinine, sulphate of iron, sulphate of magnesia, dilute sulphuric acid, and inf. of quassia.

Cancer of Liver (?).—W. C., æt. 53, innkeeper. Admitted July 13; discharged August 13. In hospital 31 days. *Unrelieved.* Has lived freely; sores on outer side of left foot 12 months; has lost flesh slightly of late; liver enlarged, slightly nodulated near gall-bladder; slight jaundice; no dropsy; tongue red.

Dilute nitric acid and bark. Haust sennæ co.

Tubercular Peritonitis.—J. J., æt. 20, druggist's assistant. Admitted January 7; discharged January 9. In hospital 12 days. *Worse.* Always temperate; previously ill, 5 months; pain, swelling, and tenderness of abdomen; costive bowels and loss of flesh; subject to piles. Œdema of feet and ankles, 1 week. Appetite good up to time of admission. Dullness on percussion all over abdomen; urine loaded with lithates; traces of albumen; no cough, hæmoptysis, or night sweats; no hereditary predisposition; 12 days later, has lost flesh much, and vomited constantly since admission; vomit now coffee ground. Pulse 125, thready. Is evidently sinking. Discharged at his own request.

Carbonate of soda and dilute hydrocyanic acid; aromatic spts. of ammonia, chloric ether, and decoction of bark; ice; effervescing mixture; brandy 4 oz.

Phthisis.—F. W., æt. 39, carman. Admitted, March 26. *Died* on April 16. In hospital 21 days. Cough 4 years; worse in winter; diarrhœa and night sweats 2 months; loss of flesh 3 weeks. On admission much cough and greenish expectoration; great dyspnœa; constant purging; flattening; dulness; prolonged expiration and bronchial breathing under left clavicle; elsewhere coarse crepitation, rhonchus, and sibilus; legs slightly œdematous; urine turbid with lithates; 6 days later, gurgling and pectoriloquy at left apex; 11 days later, dulness and amphoric blowing over left infra scapular region.

Quinine and Iron. Cod-liver oil. Syrup of iodide of iron and cod liver oil. For diarrhœa, opium, sulphate of copper, and extract of logwood, and opiate enemata.

Phthisis.—W. R., æt. 33, bricklayer. Admitted May 29. *Died* on June 26. In hospital 29 days. Acute rheumatism 9 years ago. Almost constant diarrhœa for 8 years. cough and shortness of breath 6 years; two years ago lumbar pain and hæmaturia recurring once or twice since; worse 10 days. On admission rather thin; breath short; liver tender; pulse 104; respiration 36; physical signs of emphysema; dulness and fine crepitation under left clavicle; large crepitation over lower posterior half of left lung, with dulness at base; elsewhere rhonchus and sibilus. Pus and phosphates in urine; no albumen; occasional lumbar pain; diarrhœa. Became weaker, and died on June 26.

Post-mortem.—Left apex adherent; two vomicæ in its posterior part; abundant miliary tubercle in left apex and right upper lobe; scattered tubercle elsewhere in lungs; recent lymph on pericardium; tubercular cavities filled with pus in left kidney.

Chloric ether, squills, and carbonate of ammonia (17 days). Opium and logwood (8 days). Then chloric ether and sesquichloride of iron.

Phthisis.—S. H., æt. 24, footman. Admitted August 16. *Died* August 22. In hospital 6 days. No family history of phthisis; loss of flesh 6 weeks; dyspnœa on exertion 4 weeks; cough and expectoration 3 weeks. On admission chest not very resonant; slight comparative dulness under left clavicle; small crepitation over anterior lobes of lungs, especially at left apex; sputa frothy, viscid and muco-purulent; slight œdema of legs; pulse 120.

Phthisis.—Emma H. Admitted May 13; discharged May 18. In hospital 5 days. *Unimproved.* Caries of upper part of sternum. Early phthisis.

Quinine; sulphate of iron and sulphuric acid; cod liver oil.

Phthisis.—Ellen M., æt. 12. Admitted June 29; discharged July 23. In hospital 24 days. *Relieved.* Bronchial breathing and gurgling crepitation over back of lungs. Not much emaciation. In King's College Hospital before for whooping-cough and strumous pneumonia.

Aromatic spts. of ammonia and chloric ether. Cod liver oil.

Phthisis.—Robert E., æt. 24. Admitted March 17; *died* on March 23. In hospital 6 days. Became worse soon after discharge from King's College Hospital in October last. Vomited one pint of blood about a month ago. Stools afterwards pitchy. On admission very emaciated; face flushed; pulse 120, respiration 50; over front of left lung dulness, gurgling crepitation, bronchial breathing, and pectoriloquy; over front of right coarse crepitation, bronchial breathing, and bronchial voice; spleen greatly enlarged; much nausea and vomiting. Death on sixth day after admission.

Post-mortem.—Lungs, especially the left, stuffed with tubercles and riddled by cavities; spleen large—not tubercular—waxy (?).

Sulphuric æther and aromatic spts. of ammonia; dilute hydrocyanic acid and mist effervescens; pepsine; brandy 6 oz.; turpentine stupes.

Phthisis.—Mary C., æt. 31, married. Admitted June 13; *died* on July 25. In hospital 42 days. No family history of phthisis. Previously ill one month. Cough; rapid wasting, and loss of strength. On admission very emaciated, pallid, cheeks flushed; pulse 114, respiration 36; diminished expansion of left chest, and gurgling crepitation under left clavicle and at back of lung; dulness and harsh breathing at right apex; nummular expectoration, streaked with blood; tongue slightly furred.

Quinine and dilute sulphuric acid; cod liver oil.

Phthisis.—D. J., æt. 54; laundress. Admitted January 21; *died* on January 30. In hospital 9 days. Cough and expectoration; loss of appetite and œdema of legs 5 weeks; erysipelas of legs 3 weeks. On sixth day after admission scarcely any redness of legs remaining, but delirium; dry brown tongue; retching and vomiting; pulse feeble, 126. Death 2 days later.

Post-mortem.—Much tubercle in upper lobes of lungs; lower lobes gorged. Three or four large tubercular ulcers with thickened edges in ileum—one at junction of upper two-thirds with lower third of ileum, had perforated the bowel. Pus and turbid serum in peritoneal cavity. Liver large—very fatty.

Aromatic spts. of ammonia, chloric ether and decoction of bark. Brandy 12 oz. Fomentations to legs.

Phthisis.—R. F., æt. 30; wire-worker. Admitted January 26th; discharged February 29th. In hospital 34 days. *Much relieved.* No family history of phthisis. Loss of flesh five years; gave up work six weeks ago. Diarrhœa one week. Pale and thin; left chest dull all over. Flattening; cracked pot sound; bronchial breathing; coarse crepitation; and pectoriloquy under left clavicle. Crepitation at left posterior base and apex. Right lung normal; pulse 130; six days later, amphoric breathing and metallic tinkling at left apex; gained weight while in hospital.

Sesquichloride of iron; dilute muriatic acid; chloric ether, and calumba. Cod liver oil.

Phthisis—Hæmoptysis.—J. N., æt. 15, butcher. Admitted January 28th; discharged February 8th. In hospital 11 days. *Relieved.* Small-pox 10 years ago. No family history of phthisis. Cough and expectoration three months. No loss of flesh. Profuse hæmoptysis on day before admission. On admission, dulness; large crepitation, and rhonchus under left clavicle; crepitation over left supra-spinal fossa. Free from hæmoptysis four days later.

Tannic acid and inf. rosæ. co.; turpentine inhalation; sesquichloride of iron and quassia; cod liver oil.

Hæmoptysis.—W. H. J., æt. 18; mathematical instrument maker. Admitted February 20th; discharged February 27th. In hospital seven days. *Recovery.* A brother died of phthisis. Cough two years; sputa streaked with blood one month ago. Attacks of hæmoptysis on January 29th, February 16th, and February 20th. On admission pallid; crepitation at right base behind (two days); expiration at right apex prolonged; no dulness; pulse 84, somewhat irregular. Very faint systolic bruit, loudest at heart's apex. No return of hæmoptysis while in hospital.

Gallic acid and inf. rosæ. co.; turpentine inhalations and stupes; afterwards squills, chloric ether and sesquichloride of iron.

DR. STEEVENS' HOSPITAL.

HOLT'S OPERATION FOR STRICTURE: DEATH FROM PYÆMIA EXHIBITING REMARKABLE FEATURES.

Under the care of Mr. HAMILTON.

Although the treatment of stricture by Holt's method is now generally allowed to be a valuable addition to the surgery of this disease, still it cannot be denied that it is attended with some risk, and in the adoption of a practice which has many strenuous advocates, the observation of unfortunate cases must afford a valuable lesson.

T. F., æt. 62, a pensioner, of dissipated habits, was constantly in the habit of coming to hospital with retention of urine, on exposure to cold or the commission of any excess. On some of these occasions considerable difficulty was experienced in passing a small catheter. A very tight stricture was found at the anterior part of the bulbous portion of the urethra. The difficulty of introducing instruments was frequently much increased by spasm, and the mucous membrane was always in an irritable condition. Having often expressed a desire for some permanent relief, it was determined to adopt the method of Holt. He was accordingly kept quiet in bed for some days, and the urethra dilated with cat-gut bougies, until Holt's dilator could be readily passed into the bladder. The operation was performed on Saturday, June 27th, the strictures having been burst. A catheter, No. 8 size, was passed into the bladder, the patient was treated with quinine and opium, as directed by Mr. Holt.

June 28th.—He has had some shivering during the night; he complains of severe pains in the lower limbs, with hyperæsthesia and partial loss of motor power; passes water freely and without pain; there is no tenderness or fullness in the perinæum; pulse 120, and feeble. Ordered wine and beef-tea.

29th and 30th—Appears better, but still complains of soreness and complete loss of power in the lower limbs; no rigors or sweating; no tenderness in the perinæum.

July 1st.—Very much worse; the pulse at wrist scarcely perceptible; complains of pain and powerlessness of the lower extremities; tongue dry and brown; the surface of the body is covered with an eczematous rash, having a dark areola; the mental faculties are perfectly clear; he complains of irregular pains in the chest and abdomen. The respiration became very difficult some hours before death, which occured at ten P.M.

Autopsy, twelve hours after death.—The eczematous eruption still remains on the surface. The inferior wall of the urethra has been burst at the point of stricture into the corpus cavernosum. Some pus issued from the bottom of the fissure on pressure. The cavity of the bladder was small, but its coats immensely hypertrophied, with numerous sacculi leading off from it; the ureters were much dilated; the kidneys tolerably healthy; the surface of the lungs was thickly studded over with an eruption identical with that on the surface of the body; the liver and other intestines were likewise spotted in a lesser degree; no deposit of pus could be discovered in any part. the muscular system seemed perfectly healthy; no abnormal appearance of the joints was discernable. The features of this case are interesting in some respects. The fatal termination must be attributed to a form of systemic infection, but there are many peculiarities in the symptoms, the paralysis of the lower limbs, the sensibility of the skin and muscular pains, the absence of rigors, sweating, or delirium, the appearance of the eruption on the surfaces of the body and viscera, are all uncommon. There can be little doubt that pyæmia is the chiefest source of danger in this operation, and the occurrence of suppuration in such a structure as the corpus cavernosum, must be a condition specially favourable for its development.

CITY OF DUBLIN HOSPITAL.

CASES UNDER THE CARE OF MR. CROLY.

Case 1.—RETENTION OF URINE IN A CHILD, CAUSED BY A CALCULUS IMPACTED IN THE URETHRA: REMOVAL OF CALCULUS BY OPERATION.

S. W., aged two years, a coachman's son, was carried to the hospital by its mother. Mr. Croly was in the extern prescribing-room at the time, and on inquiry ascertained that the child (who was in great agony) had not passed any urine for 18 hours. On examination the bladder was found to be enormously distended, and there was partial priapism; the child had been treated by warm baths, stupes, and various medicines, without relief, before coming to the hospital. The mother also stated that the child had been delicate from its birth; had convulsions, and that his water stopped three days previously, but he got relief on that occasion from a warm hip-bath. The child had congenital phymosis. Mr. Croly made a small incision with a sharp-pointed bistoury (guarded by a director, curved near the point) at the upper part of the prepuce, and was then enabled to pass a probe into the urethra, which touched a hard substance, about an inch from the orifice. The urethra was so very small that it was found necessary to enlarge the orifice; this having been done, the calculus was seized with a small urethral forceps, and extracted; the stone was the size of a pea, and consisted of lithic acid; the urine came out with a gush, to the instant relief of the little sufferer, who was kept in the child's ward until the following day.

Mr. Croly directed the attention of the pupils to this interesting case, and mentioned the causes of retention of urine in early life—congenital phymosis being the most common; he impressed on them the necessity of making a careful examination in such cases, and not adopting routine practice, which was so uselessly tried in the present instance, previously to the child's admission into hospital.

Case 2.—IMPERFORATE ANUS (ATRESIA ANI): OPERATION.

A. C. was recommended to Mr. Croly by a medical friend. The infant had been dosed with castor-oil, and as no motion came from the bowels, the nurse, at length, sought medical advice. The doctor at once discovered that there was an absence of the anus. The child cried incessantly. On examination, a bulging was observed in the anal region—the integument was apparently dark-coloured, owing to the meconium. Mr. Croly placed the child in the lithotomy position, and made a crucial incision into the part. A large quantity of meconium escaped. The case terminated satisfatorily. Mr. Croly mentioned to the pupils that this case is an illustration of the simplest form of imperforate anus, in which the rectum is perfect, and merely closed by integument, only requiring for its cure careful incision. The more serious forms of this malformation, he said, consist of the gut ending in a *cul-de-sac*, or communicating with the urethra, bladder, or vagina; the rectum being totally absent in the worst variety of the malformation.

Case 3.—EQUINO-VARUS IN BOTH FEET: TENOTOMY: FEET STRAPPED INTO POSITION WITH SOAP-PLASTER.

A male child, aged six months, was admitted, with its mother, into hospital for the purpose of having the operation for club-foot (*equino-varus*) performed. Mr. Croly divided the tendons in the following manner:—The child was placed prone on the lap of one of the pupils, the left foot was grasped, and the heel raised, to relax the tendon. A tenotome was introduced, flatwise, at the edge of the tendo-Achillis, and passed superficially to the tendon beneath the integument. When the point of the instrument was felt (with the index-finger) to have passed the tendon, the edge was turned towards it, and the heel was depressed; by slight pressure on the back of the blade of the knife the tendon was divided, and the usual crackling sound was heard. The blade of the knife was again turned flatwise, and then withdrawn; a drop of blood escaped. A small compress of lint was placed on the puncture, and fixed with a strip of adhesive plaster. The tendo-Achillis of the other foot was divided in a similar manner, and as the tendon of the tibialis anticus was very tense, it was also divided subcutaneously (in each foot), about an inch above its insertion.

In three days, Mr. Croly strapped each foot into proper position in the following manner:—Long slips of soap-plaster were cut, the end of each piece was placed around the dorsum of the foot, so as to get a good purchase, and carried upwards and outwards, under the sole, and fastened to the fibular side of the leg. Straps of figure-of-8 shape were also alternately applied around the foot and ankle-joint.

Mr. Croly demonstrated, in a clinical lecture, the various forms of talipes, and the method of treatment suitable to each case. He advised the operation to be performed in very early life, before the bones of the foot become altered in shape. He exhibited dried specimens of feet affected by talipes, in which the neck and head of the astragulus were much distorted.

The treatment by strapping was strongly recommended, and the various boots in use were also fully explained to the class.

Literature.

SPINAL DISEASE.[1]

A SUBJECT that has long been particularly interesting to the general practitioner, and that has had much light thrown upon it by those who have taken it up as a specialty, is that of spinal disease. When, therefore, Dr. Little, who is the father of Orthopædy in this country, undertakes to give a *résumé* of his experience in the treatment of spinal curvature and weakness, there is little for the critic to do but announce the fact, inasmuch as the authority of the writer is such that few would venture to question it, while to lay all its conclusions before our readers would require too much space, and involve some injustice, as too much of the book would have to be reprinted.

---

[1] On Spinal Weakness and Spinal Curvatures; their Early Recognition and Treatment. By W. J. Little, M.D., late Senior Physician London Hospital, &c. London: Longmans, Green, and Co. 1868.

Those questions on which reasonable differences of opinion have prevailed, are all fairly and carefully considered, and no one will take exception to Dr. Little as the judge, who is best able to sum up the matter. The founder of the Royal Orthopædic Hospital, he is also the founder of the school of orthopædics in this country, and has for many years unquestionably been its head. From him there is, so to speak, no one to whom to appeal, and we are consequently so much the better pleased to have his summing up in a small compass like this well-written work. We regret that we should find our experience coinciding with Dr. Little on a point which we commend to our readers. He finds that the majority of medical men do not possess clear ideas of the pathology and diagnosis of spine affections. It is because we have so frequently found deficiency of knowledge with a desire to become acquainted with the subject that we are desirous of seeing this work very widely circulated.

The "early recognition and treatment" of such cases is of the utmost importance, since at later periods we cannot hope for cures, though the deformities may be evident enough. We, therefore, sincerely trust that those who may be called upon to treat such cases will not omit to master the lucid work before us.

The existence of a specialty of orthopædy is perhaps one of the best answers to those who object to specialism. It is impossible to deny that without some persons with large opportunities making this branch a special study, it could not progress. The general practitioner has not the time to elucidate the points that have been so ably investigated by the specialists. We do not say that other studies should be neglected. Dr. Little himself is an admirable instance of the true scientific position of the specialist. While for twenty or thirty years or more, he has been labouring in this department, he has also occupied himself with others. While perfecting orthopædics, he has been earning renown as Physician to the London Hospital, and Professor of the Principles and Practice of Medicine at its school; and although he has now retired from the general hospital as well as from the special, carrying with him the respect and admiration of colleagues and students, it is happily only to give more time to the cares of private practice, while he leaves the opportunity for younger men to follow in his footsteps. When all the specialities shall be studied after this manner, we may look for still greater progress. The combination of extensive study and experience of disease brought to bear upon one particular branch is the true solution of all specialities. It is this which elevates every branch as much as the mere routine practice of it degrades it.

We have left no room to enumerate the chief points treated on in Dr. Little's book. That is the less regretable since, as the author has condensed his observations into 120 pages, we may anticipate that all our readers will take an early opportunity of reading the book itself.

PLASTIC SURGERY.[1]

We have in a neat little volume from the United States, a reprint from a report in the transactions of the Illinois State Medical Society for last year, which does great credit to that western association. Dr. Prince has devoted much attention to plastics, and he is anxious not only to classify the subject on an easily intelligible plan, but so to speak of it that each division may have an appropriate name, and be easily designated. Certainly precision of language in surgery generally is most desirable, and in a branch which like this has been comparatively neglected, no better service can be rendered than contributing to such exactitude. Nomenclature should be guided by some definite principles, and classification should not be adopted in a hap-hazard way. Dr. Prince contributes towards rendering the description of plastics more easy and more precise. and therefore deserves the thanks of all interested. We should add that Dr. Prince's descriptions are profusely illustrated by woodcuts, and that the essay contains a full account of the present state of plastic surgery.

PATHOLOGICAL ANATOMY OF THE UTERUS.[2]

We are glad to announce that Professor Klob's *magnum opus* will soon be at the service of the English student in his own language. The first volume devoted to the uterus has already appeared, and the rest will no doubt soon follow. It is our transatlantic cousins who have undertaken this translation, and we are much indebted to them for it. It can be obtained in London from Trübner & Co. The translation is carefully done.

MEDICAL JURISPRUDENCE.[1]

We have lately studied the new edition of Dr. Guy's Manual of Forensic Medicine with particular care, and have now to pronounce upon it a very favourable opinion. Of all the books that the student may carry home, in the holidays, to refresh his memory on the subjects of the summer course, this is one of the best, and of those that should be studied by gentlemen preparing for their examinations, it is one of the most reliable.

The book has always been distinguished for presenting principles in a concise form, and not over-burdened with useless *minutiæ*. The condensation which the author achieved in his first edition has been amply rewarded by the call for a second and third.

In the new edition the number of illustrations are considerably increased, and some of the new ones are very striking.

As might be supposed by those familiar with Dr. Guy's labours, the subject of sublimation is presented very fully to the reader in a chapter which everyone should carefully peruse. Nearly half the manual is taken up with Toxicology, the growing importance of which, few will be ready to deny. We strongly recommend this portion of the work.

The chapter on the methods of procedure gives distinct directions, and in as small a compass as possible describes the practical duties that have to be performed. But if about to select as a specimen, the best chapter in the book, we think, we should take the last, which treats of the "Diagnosis of the Poisonous Alkaloids and Analogous Active Principles." Here is a subject in which every practitioner is interested, and it is worked out in the author's most careful and satisfactory manner.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 29, 1868.

MOVEMENT OF TROOPS IN INDIA.

AMONG the movements of troops to take place during the ensuing winter, the military papers intimate the following, namely:—C Battery 16th Brigade Royal Artillery, from Barrackpore to Saugor; D Battery 16th Brigade, from Barrackpore to Allahabad; 2nd Battalion 60th Rifles, from Fort William to Darjeeling and Benares; a regiment from England to Fort William (Cape Route corps). There may not at first sight be much in these brief notices to call for remark in this place; yet in reality they have a very important bearing upon the question of health and efficiency of our troops in India.

Experience had, many years ago, demonstrated the impropriety of retaining at Calcutta or other stations in the lower provinces of Bengal, troops, whether as recruits or entire regiments, newly landed in the country. The practice had therefore been abandoned, and every exertion made by the responsible authorities to push on towards the north-west provinces each regiment or "draft" as it arrived. In the days of the mutiny, when sanitary considerations had to give place to the life-struggle for supremacy, this very judicious rule had to give way to the necessity of the times; but now, when profound peace reigns from one end of the country to the other; when sanitation is a "household word" among the *authorities* in India, it does seem strange that, in ordering the retention in such places of young and newly-arrived soldiers, they thus recur to a practice which, as may be read by themselves in their own official records, had already been attended by most disastrous effects to health and life.

[1] Plastics: a new classification and brief exposition of Plastic Surgery. By David Prince, M.D. Philadelphia: Lindsay and Blakiston. 1868.

[2] Pathological Anatomy of the Female Sexual Organs. By J. M. Klob, M.D., Professor at the University of Vienna. Translated by Joseph Krammerer, M.D., and Benj. F. Dawson, M.D. Vol. I. New York: Moorehead, Simpson, and Bond. London: Trübner and Co. 1868.

[1] Principles of Forensic Medicine. By William A. Guy, M.B., F.R.S. Third edition. London: Henry Renshaw.

On the amalgamation of the Indian and Royal Artillery, the two batteries just mentioned were for the first time formed. This was in the cold season of 1862. A few old soldiers were transferred to those batteries, and the numbers filled up by young men newly landed in India. The batteries were sent to Barrackpore, a low-lying station immediately adjoining a large tidal river, across which the prevailing wind blows *towards them.* The natural result followed; the rates of mortality and sickness among them speedily became so high that attention was drawn to them, and statistics showed that a station which had previously enjoyed a high reputation, had now the unenviable notoriety of having one of the highest death-rates of all in the Bengal Presidency. Such is the station from which the batteries are now about to be moved after a continuous residence of nearly six years.

Residence in Fort William, as stated before the Royal Commission, has for the recruit been *most disastrous.* No doubt everything that can be effected is done to place the troops quartered there in as favourable circumstances as they can be, and an example might profitably be taken in extending to places nearer home some of the sanitary measures that are there employed. Those measures do unquestionably conduce much to health, but they cannot wholly counterbalance the effects of the hot, moist, and exhausting climate; continuous exposure to terrestrial malaria, unwholesome emanations wafted towards the fort from the foul river, festering with corruption, that glides past its walls, not to speak of those from the surrounding ditch, a part of which is used as a latrine by the natives, and flushed by the tide. Neither can they effectually remove all risk from cholera, a disease which there is ever present, and ever ready to be lighted into activity under favouring circumstances; nor can they impose sufficient restrictions upon the facilities for vice and dissipation presented by the neighbouring bazaars and dens of iniquity that abound in Calcutta.

Surely, then, Fort William, abandoned as it has already been as a suitable station for young soldiers, and possessing these various elements of disease, is no better adopted for the newly arrived and inexperienced than it has ever been. It is quite the case that one regiment may escape without great mortality, or even two; yet those who practically know India are well aware that even if troops in the lower provinces escape an actual outburst of sickness, not only is the proportion large of men who have to be invalided on account of illness, but that the constitution cannot and does not become robust in those who during adolescence and early manhood have lived under such circumstances as in those more favourably situated.

It has been said that the system of overland transport of troops, requires that regiments should now begin their service near the sea, and "work upwards," so as to be the more readily despatched *via* Bombay on completing their Indian tour. This reason cannot be accepted. Nor, even had it any other circumstance to recommend it, ought it to hold good when clogged by the dire necessity, increased by the measure of retaining young troops in the very part of India where their risks of mortality are greatest, and their prospects of preserving health the smallest.

ELECTION OF THE KING'S PROFESSOR OF PHYSIC IN DUBLIN.

On Friday, the 24th instant, this election was held in the Hall of the College of Physicians in Dublin, the President, Dr. Churchill, in the chair.

The candidates were—Drs. H. Kennedy, Freke, Moore, and Foot, all Fellows of the College; and Dr. John Maule Sutton, of Cheltenham.

The following Fellows were present, were duly sworn by the Rev. Dr. Lloyd, Provost of Trinity College, and voted (by ballot) at the election:—Drs. Adams, Apjohn, Atthill, Banks, Barker, Beatty, Belcher, Burke, Churchill, Croker, Dwyer, M. Eustace, Foot, Freke, Gordon, Guinness, Rev. Dr. Haughton, Drs. Hayden, Head, Hudson, Jennings, Johnston, H. Kennedy, Law, Little, Lyons, M'Cready, Mollan, Moore, Ringland, Sinclair, Smith, Steele, Stokes.

The voting (we understand) was as follows:—

1st Ballot.—To select three out of five, each Fellow voting only for one candidate—Kennedy, 4; Freke, 9; Moore, 17; Foot, 4; Sutton, 0. Drs. Kennedy and Foot being equal, the President gave his casting vote in favour of the former, on the ground of seniority.

2nd Ballot.—To select two out of three—Kennedy, 3; Freke, 13; Moore, 18.

3rd, and final ballot.—Freke, 15; Moore, 19.

The President accordingly declared Dr. Moore duly elected King's Professor of the Practice of Physic in the City of Dublin, on the foundation of Sir Patrick Dun, and he was immediately sworn into office.

We have no doubt of Dr. Moore proving a worthy successor to his excellent predecessor Dr. Banks; and we are satisfied that the choice of the Fellows of the Dublin College of Physicians will do anything but discredit to the "School of Physic in Ireland."

SPECIALISTS AND SPECIALISM.

A few weeks ago we protested against the wordy war waged by some of our contemporaries against specialism in all its forms. We now repeat that protest, since the unjust accusations levelled against individuals continue to be repeated in a variety of forms. It is strange that we should so constantly see an exhibition of personal animosity under the pretence of discussing principles.

Nothing can make our profession so contemptible as the personal squabbles indulged in at the expense of truth. Nothing is more likely to deprive it of its just influence than the continual statement of one side of a question, and the obstinate suppression of the other. It is, indeed, lamentable that such injustice should prevail, and that men should be suffered to "stab each other in the dark," while pretending to expound public policy.

Yet it has ever been so. Medicine as a profession is divided against itself, and for that very reason is devoid of influence. It is not so with the sister profession of law. Who ever saw the same indecent rivalry and ridiculous jealousy between lawyers? Still less is this the case with legal writers and contributors to legal journals. The attempt to run down men who exercise any special branch of medicine is not more likely to succeed than the attempt to ruin special hospitals which has been made by the same parties.

Why, let us take an example or two of special institutions. Who will deny that Ophthalmic Hospitals have conferred immense benefits on humanity ?—that they have helped to bring ophthalmology to its present state of perfection. It is true that Travers, Lawrence, and other illustrious names, show that general surgeons may do much for a special branch, and have done much for Ophthalmic surgery, but yet the fact remains that the greatest progress for the last 20 years or more is to be traced distinctly to Ophthalmic Hospitals.

Shall we then, to please a clique, shut up these charities, and go back to the old attempt to grasp everything within the walls of one hospital ? The public, as we have often observed, has long ago answered this query in the negative, and we see no reason for challenging the verdict.

Another example—what about Consumption Hospitals ? Would our contemporaries destroy all the charities devoted to diseases of the chest ? Would they deny that men who practise scarcely anything else, are, to all intents and purposes, specialists ? Is it not a fact that these men have contributed largely to the progress of science—that they have even made important discoveries ? Why, then, this hostility, this petty jealousy of every institution; and this constant war with all specialists ?

There are reasons which it is not our purpose to-day to dilate upon. We repeat once more our protest against the injustice that is being perpetuated, and we challenge a verdict on the two classes of institutions we have mentioned—Ophthalmic Hospitals and Consumption Hospitals.

"NOCTES, CŒNÆQUE DOCTORUM."

"Do what we say, but not what we do," is a time-honoured adage or proverb, which has been attributed to the jolly monks of mediæval times, who followed the rule of St. Benedict, but who, for all that, on certain occasions, were wont to refresh themselves at night after the professional labours of the day ; to chant the psalm, "Qui habitat in adjutorio Altissimi" at Compline ; and then towards the conclusion of a good supper, to sing "We won't go home till morning."

Even so is it with some doctors, learned doctors—for all doctors are learned of course ; they solemnly warn their patients against late dinners, and extra good dinners ; against "made dishes," &c., &c. ; but few like good dinners better, or eat them oftener (when they can get them) than our brethren ; and must we confess it ? than ourselves !

In former days there was in Dublin a society, which was known as "the Medical and Philosophical ;" but which, for the greater part of a century, has existed as a medical dinner club, under the same name, we believe, though in the Dublin medical venacular it is jocosely called "the Philœsophageal." Also in the last century the Fellows of the Dublin College of Physicians every St. Luke's day at their annual meeting voted £100 to the President to purchase claret for their entertainment. For many years, this admirable custom has been abolished ; but although of late it has been not unusual for the President of that College to entertain his brethren, the Fellows, in his own house, yet it is due to Dr. Beatty, we believe, to state, that he, during his Presidency, inaugurated what promises to be a time-honoured custom, and gave a handsome banquet to the Society of which he was the head, in the College Hall itself.

The present President of the King and Queen's College of Physicians in Ireland (Dr. Churchill) maintained this wholesome usage by entertaining in the College-hall, on the evening of Tuesday, the 21st instant, the following Fellows: —Drs. Adams, Apjohn, Atthill, Banks, Beatty, Belcher, Burke, Croker, Cruise, M. Eustace, Foot, Freke, Gordon, Guinness, Haughton, Hayden, Head, Hudson, Jennings, Johnston, Sir Robert Kane, H. Kennedy, Law, Little, Lyons, M'Cready, Moore, Ringland, Sinclair, Smith, Steele, Stokes, and Travers.

In addition, the following guests were present:—The President of the Royal College of Surgeons in Ireland (Mr. Porter), the Right Hon. the Lord Mayor, (Sir William Carroll,) Licentiate of the College ; Dr. Dane, P.M.O. Dublin ; Inspector-General Mouat, V.C. and C.B.; and Dr. Churchill, junr.

Dinner being ready, and the guests having repaired to the Convocation-hall from the Library, which had served for an ante-room ; one of the Fellows, the Rev. Professor Haughton, M.D., "blessed the board" (we use the good old English phrase) in the language of colleges, that tongue which is in daily use in medical practice, and which is popularly and charitably supposed to be on the tips of the fingers of every M.D.

The form used was partly that of Trinity College, Dublin, with an extemporaneous addition by the Reverend Doctor, and was significant as well for the open advocacy of the use of Latin on public medical occasions, as for the assertion of the time-honoured relation of this college to its *alma mater*, Trinity College, Dublin, from which it sprang more than 200 years ago.

The dinner, which was supplied by Mr. Murphy, late of Mitchell's, was of the best description; and was, to use the cant gastronomic phrase, "replete with every delicacy of the season."

At its conclusion the Reverend Dr. Haughton said Grace, somewhat after the fashion of Lincoln's Inn. We give the two verses as recited by Dr. Haughton, that they may be placed on record, and used at future dinners as "the Dublin College of Physicians Use."

Dublin College of Physicians Use.

Benediction Before Meat.

Miserere nostri Te quæsumus, Domine, atque his tuis donis quæ de tuâ benignitate sumus percepturi, benedicito, per JESUM CHRISTUM Dominum nostrum.—*Amen.*

Grace After Meat.

Benedictus Dominus benedicatur, pro his atque omnibus ejus donis, per JESUM CHRISTUM Dominum nostrum.—*Amen.*

The President proposed the health of the Queen, and afterwards that of the Royal College of Surgeons in Ireland. To this latter the President of that body responded, and gave the health of the host, which was duly received.

Next the host gave "The University of Dublin," which was responded to by Dr. Stokes, who gave "The School of Physic, and Professor Haughton," the latter gentleman returning thanks. The toast of "The Queen's Colleges" was responded to by Sir Robert Kane, and that of the Army by Dr. Dane, P.M.O., and by Inspector-General Mouat, after which Dr. Beatty, by request, favoured the company with an admirable specimen of vocal music, "Sicut est mos," and the company retired after spending a very pleasant evening. Floreat Collegium Medicorum Regis et Reginæ in Hiberniâ.

Notes on Current Topics.

The Duke of Edinburgh.

ADDRESSES congratulating his Royal Highness on his recovery from the murderous attempt of the assassin, were presented to the Duke of Edinburgh by the Ancient Scottish Hospital, and by the Highland Society of London, on Tuesday, the 21st instant. The addresses were presented respectively by the Dukes of Montrose and Richmond. Many gentlemen attended, most of them appearing in the Highland costume. Amongst those present were several members of the medical profession—viz., Drs. Scott Alison, and Ramsay, Physicians to the Scottish Hospital;

Dr. Stuart Tulloch, and Dr. McKinnon, C.B., of Netley Hospital. We understand the Duke, though looking somewhat thin, appeared to be in excellent health and spirits, and that his expression was one of great intelligence and activity.

St. Andrews Medical Graduates' Association.

We have received the first volume of the *Transactions* of this association. It is somewhat tardy in making its appearance, but contains much interesting matter. The papers of last year's session, some of which we reported in full, and of the others gave abstracts, are here published, with the revision of the authors.

It is pretty clear that the volume has been kept waiting for one paper. This is scarcely just to other writers, and we would advise the editor on another occasion to be more severe, and omit altogether contributions that are not completed within a reasonable time.

There is a list of members and their appointments, but this we observe is not complete, as we could, from memory, make several additions and corrections.

The Registrar-General's Quarterly Return for Ireland.

It is but of late that registration in this part of the United Kingdom has reached anything like a reliable condition, and even now it is hard to say whether the returns can be, in all cases, implicitly trusted as indicating the actual state of things. There are feelings and influences at work which baffle the attempt to arrive at a degree of accuracy such as we attain in England. Still, making every concession, we have reason to believe that we may congratulate our Irish readers on the present condition of their country in a sanitary point of view. We refer chiefly to this, though there are other particulars in the report of equal concern, such as emigration, pauperism, the price of food, and others as well. From the estimate, it appears that the deaths in the first quarter of 1868, were fewer than in the same quarter in each of the previous four years, and less by five thousand than they were in the first three months of 1867. It will be remembered that there was a great difference in the temperature of the two winters thus compared, which may partly, perhaps mainly, account for the favourable difference recorded in the death-rate. Different medical men in various districts have supplied notes from which a large part of the return has been made up, and on their authority, it appears that the adoption of sanitary regulations has had its effect, in many places, in promoting the improved state of the public health. We cannot, however, but regret to state, on the same authority, that a large portion of the population are culpably neglectful in these particulars; exposing themselves and those who dwell around them to danger, by suffering every species of filth to accumulate and rot under the very walls and windows of their dwellings, and taking no care to avoid infectious disease, or to check its progress when it has made its appearance. We would urge upon every one in a position of authority or influence to use his power with his equals and dependants, and awaken them, if possible, to duties upon which their own and neighbours' lives may depend.

Prevention of Cruelty to Animals.

The Earl of Harroby took the chair at the annual meeting of this society, which was held at Willis's-rooms on the 18th instant. From the report, it appeared that 994 convictions had been obtained, being 200 in excess of last year. The report stated also that vivisection was decreasing in France, chiefly through the operations of the society. The noble chairman said he did not consider the increase of convictions as a proof of the increase of offences, but of the increase of detection by the officers of the society. He was glad there was a decrease of the practice of vivisection in France, and regretted that bull-fighting should have been introduced there. Another great scandal, he said, was the treatment of cattle in the vicinity of London. He hoped it was not too late, even in the present session, to make at least a beginning in a better system with respect to the slaughtering of cattle than that which for so many years had been the scandal of the metropolis. The Earl of Romney thought the rich and the poor were both alike in the matter of cruelty to animals. The one set the example, and the other followed it. He believed there was great thoughtlessness in the cruelty inflicted in many cases, and instanced driving by constantly pulling the reins and bit, the use of the whip, and the absurd bearing-rein, which unfitted horses for their work. Several others addressed the meeting, remarking, among other things, on the cruelty to cattle sent from the sister country, and to dogs by the use of the muzzle in the present sultry weather.

Accidentally Poisoned.

In the *Times* of July 20th, is recorded a melancholy instance of a young lady accidentally poisoned by an over dose of strychnine. It appeared that the deceased had been directed by her medical adviser to take at mealtimes five drops of liquid containing strychnine, and was supplied with a bottle in which was an ounce of liquid containing four grains of that poison. On Thursday evening, the lady put five drops of the liquor strychniæ into a small bottle of water, just like the one that held the liquor itself, then by mistake she took up, and carried down with her this last named bottle instead of the one containing the mixed drops, and when seated at the table, poured out and drank off its contents, which appear to have contained about three grains of strychnine. In ten minutes the poor lady was dead, with all the symptoms of poisoning by strychnine.

The coroner (Dr. Lankester), at the inquest, condemned the practice of vending poisonous medicines in ordinary bottles, a matter evidently still requiring attention, although many leading chemists always dispense poisonous remedies in bottles of peculiar shape, so that the bottle is known if taken up in a dark room. We would for our part venture to doubt the wisdom of allowing as much as four grains of strychnine (*i.e.*, one fluid ounce of the liquor strychniæ of the Pharmacopœia to be in the possession of any patient at one time; surely it would be better and safer to dilute the medicine, and give a dose of one tablespoonful or more in such a diluted state.

A movement has commenced for employing female nurses in lunatic asylums where males are at present employed. It is said that the change, so far as attempted, has proved beneficial to the patients. Drs. Maudsley and C. Browne support the innovation. The advocates of female labour would do well to watch this apparently suitable opening.

It is arranged that a Royal Commission shall investigate the state and operation of the laws relating to sanitary questions.

The Medico-Psychylogical Association has fixed its annual meeting for the 4th August, at the Royal College of Physicians, London. The same day the British Medical Association meets at Oxford.

The fee for registration for members of the General Councils of the Scottish Universities has been reduced by the House of Lords to £1. When the Bill left the Commons it was 30s. We believe the change is the result of the representations of the Scottish Universities' Union.

On the 10th of last month, as our readers are aware, Mr. Pim gave notice "that he would ask the Chief Secretary for Ireland when he would be able to lay upon the table of the House of Commons, the correspondence between the Treasury, the Irish Government, and Dr. R. McDonnell, late Medical Officer of the Mountjoy Prison, relative to the change in the medical management of that prison, by which he was deprived of that office."

We look anxiously for this correspondence, which we hope may clear the authorities from the suspicion of having "hunted down" a deserving public officer, merely because he did not run exactly in the groove they desired. We have, meanwhile, learnt with great satisfaction that, although the Lords of the Treasury at first declined to give Dr. McDonnell any compensation, on the ground that he did not give his whole time to the public service, yet, on the representation of Lord Mayo, they have reconsidered the question and granted Dr. McDonnell a pension. We look upon this as a good omen for the cause of the Dispensary Medical Officers, and hope that the Chief Secretary may remember that the same arguments which were applicable to Dr. McDonnell's case, and which caused him to exert himself so strenuously on his behalf, are equally applicable to the case we have mentioned.

Foreign Medical Literature.

PROFESSOR BAMBERGER ON ACUTE POISONING WITH PHOSPHORUS.

(Reported by C. Arbo.)

Translated from the *Norsk Magazin for Lægevidenskaben*, xxii. Bind., 3 Hefte, Christiania, 1868, by

W. D. MOORE, M.D.Dub.et Cantab., L.K.Q.C.P.I., M.R.I.A.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

In the Prague Sessional Medical Report for 1866, is a lecture by Professor Bamberger on his investigations respecting acute poisoning with phosphorus, which, as a communication on the subject by one of the greatest medical celebrities of Germany, seems likely to throw some light on the rather obscure opinions which still surround it, and will, therefore, probably prove interesting to our readers.

Bamberger referred to the increasing frequency of these poisonings, due to the ease with which the agent is now procurable. Thus the reporter saw, during nine months' stay in Vienna, three cases of acute poisoning with phosphorus; the most frequent poisonings were with cyanide of potassium, of these, in the same space of time, eight instances occurred.

Without going further into the details in a forensic point of view, Bamberger wished to bring forward the difficulty of demonstrating the existence of phosphorus poisoning in the dead body, indeed sometimes it is purely impossible to demonstrate it.

When a long time had elapsed since the phosphorus had been taken, when a part had been again discharged by vomiting, and where what remained was, by reason of the great affinity of phosphorus for oxygen, changed into various products of oxidation, the chemical demonstration would be probably very difficult, and the anatomical changes produced by the poisoning, which might corroborate the correct diagnosis, would not in all cases be characteristically marked, or free from sources of fallacy. This is shown, among others, by those cases published by Rokitansky, and expounded as acute steatosis of the liver and kidney, as well as by the analogous cases published by Wagner, of Leipzig. Some of these were certainly referrible to phosphorus poisoning, while, with respect to others, this is doubtful, and it must, therefore, be left undecided, whether such an acute degeneration of the liver and kidneys may not depend upon other causes.

But the medical interest of the subject is still greater than the forensic. Phosphorus poisoning is characterised, as is well known, by a peculiar complex of symptoms: considerable depression of the nervous system, striking diminution of the activity of the heart, ecchymoses in all organs, jaundice; and fatty degeneration of the liver, kidneys, muscular structure of the heart, and other organs. If we endeavour to discover the cause of these phenomena, we must admit that the explanation of them is in many respects obscure and difficult. Leyden and Munk, who have worked out the subject in detail, and have instituted numerous experiments upon animals, have undoubtedly contributed to clear up the matter, but the results of their labours have also given rise to much doubt.

This had led Bamberger to again investigate the matter; in doing so he started from definite points of view, and proposed to himself certain questions which permitted him, with some probability, to expect a satisfactory result—namely:

1. In what chemical form does phosphorus act injuriously on the system?
2. What are the causes of the fatty metamorphosis of the organs?
3. What treatment is to be substituted for the almost wholly inactive plan hitherto in use, with a prospect of a better result?

Respecting the first point, physiologists had not been at all agreed, as the great variety of opinion expressed by the several writers sufficiently proves. At one time phosphorus, as such, was accused of being the poisoning agent; at another, the lower degrees of oxydation, as hypophosphorous and phosphorous acid. Schuchardt assumed that the phosphorus acted injuriously in the system by the formation of phosphuretted hydrogen. Munk and Leyden accused phosphorous acid of being the injurious agent. Schuchardt's view is, indeed, generally given up, as it is not conceivable, that from the presence of phosphorus in the stomach, any other than combinations of oxygen with that element should arise.

Munk and Leyden evidently went farthest in their opinion that the oxidation products of phosphorus, especially PO_5 acted injuriously; they asserted plainly that phosphorus in the stomach could exercise only a corrosive action, and had in itself no general effect. They based their argumentation upon the facts that

(*a*.) Phosphorus was not soluble in the body.

(*b*.) That it did not exercise any essential action upon organic substances, for example, blood.

(*c*.) That it was not demonstrable in any organ after poisoning had taken place.

Neither were the lower degrees of oxidation of phosphorus injurious, as in experiments upon animals with hypophosphorous acid they had arrived at results, essentially different from those obtained in phosphorus poisoning. On the other hand, by injecting phosphoric acid into the jugular vein they developed phenomena, analogous to those in phosphorus poisoning: diminution of the heart's action, ecchymoses and petechiæ, &c. They therefore assumed that *the first effect of phosphorus in the stomach was only local and corrosive, but that on the corroded part, oxidation forthwith took place with the formation of phosphoric acid, which entered the blood in the nascent state, and dissolved the blood globules.* The ecchymoses, the dissolved state of the blood, and the bloody urine in persons poisoned with phosphorus, are adduced as proofs thereof.

The starting point of these deductions was, in Bamberger's opinion, evidently false; for it is established by experience that general intoxication has occurred with phosphorus without the slightest corrosive action having been found in the stomach and intestines.

Neither did Bamberger, in numerous experiments upon animals, find any corrosion of the mucous membrane, and yet fatty degeneration in the organs existed in an extreme degree.

Neither was the second part of their assertion correct, that the blood globules were dissolved. Bamberger took, in animals after several days intoxication, blood from different vascular parts, but on microscopical examination, he found not the slightest difference from the blood of healthy animals. A similar negative result was obtained from freshly drawn blood, left for a long time in a cup in contact with phosphorus; not even did the blood globules immediately surrounding the phosphorus, exhibit any change. Nor, when the vapours of phosphorus were passed for a long time, by means of an aspirator, through recent blood, did the blood-corpuscles manifest any change, the blood became only of a lighter red, which might be regarded either as an effect of the oxygen in the atmospheric air passing through at the same time, or as the ozone action of the phosphorus.

It is true that in dead bodies after phosphorus poisoning the blood is found less coagulable, or entirely fluid; but this is not the case until a considerable change of the heart, liver, kidneys, and other organs has occurred, when the whole system is in a great degree implicated; and this alteration of the blood is then not to be regarded as primary, but as a result of the general affection of the organism. When the blood was taken from the animals experimented on at an earlier period, it was not at all changed.

The same is also the case in the different dyscrasias, as typhus, pyæmia; the alterations of the mass of the blood met with in the dead body are not present *à priori*, but are to be regarded as the result of the manifold disturbances developed during the course of the disease. The action of the phosphorus is therefore not to be compared with that of arseniuretted hydrogen, or of the mineral acids, which produce destruction of the blood-corpuscles, nor with that of carbonic oxide gas, which displaces the oxygen of the blood-globules, and enters into an inseparable combination with the hæmo-globuline, which gives the characteristic spectral phenomena. The alterations of the blood produced by phosphorus do not belong to the grossly material; they ought much rather to be classed with those still unknown changes, which the different contagions and miasmata, or the smallest quantities of certain poisons, produce in the blood.

With respect to phosphuretted hydrogen, hypophosphorous acid, and phosphorous acid, he found Munk's and Leyden's experiments decisive.

That phosphorus, as such, should produce the well-known effects in the system, was, as has been mentioned, denied partly for this reason, that investigators had not hitherto succeeded in chemically demonstrating its presence in the blood or in the organs. This, he thought, was due to the unsuitableness of the method of investigation, and it was desirable, therefore, to find one which should be reliable also for small quantities of phosphorus, and such is that quoted by T. Scherer, in his "Lehrbuch der Chemie."

Phosphorus, both in substance and in the form of vapour, reduces the oxides of the noble metals; strips of paper, moistened with a solution of nitrate of silver, become rapidly black with phosphorus with the formation of phosphuret of silver, phosphoric acid, and the separation of metallic silver.

Now, if we have an organic fluid—for example, blood—to examine for phosphorus, we must in the first place satisfy ourselves that no sulphuretted hydrogen is present, by testing it with nitro-prusside of sodium or acetate of lead. If no sulphuretted hydrogen be present, a strip of paper moistened with a solution of nitrate of silver is fastened to the cork in the bottle in which the fluid to be examined is, and this, if necessary, is slowly heated in the sand-bath. If phosphorus be present the paper is soon blackened. We may also convince ourselves of the presence of the phosphoric acid formed at the same time. On boiling the strip of paper in water, the nitrate of silver also taken up is precipitated with hydrochloric acid, and the residue is tested for phosphoric acid with molybdate of ammonia, which is a very delicate test of the presence of that acid. Fresenius and Neubauer have had to object to this method, that all the phosphorus is not taken up, as the greater part of it combines with the silver as phosphuret of silver, which is insoluble in water; aqua regia must therefore be employed, by which, however, the paper is destroyed, which itself, again, contains traces of phosphoric acid, probably combined with lime. To avoid this Bamberger employed heated asbestos, whereby not only a source of error was eliminated, but also the vapours of phosphorus obtained larger surface of contact.

To ascertain the law of diffusion of phosphorus, Bamberger instituted a series of experiments. A cylinder was filled with water and air, or with water alone; a small piece of phosphorus was introduced into it, and it was then tied over with an animal membrane (pericardium of a man, or a pig's bladder or vegetable parchment), and placed in connection with another cylinder filled with fluid. Not long after the outer fluid became turbid, presented the smell of phosphorus, and exhibited Scherer's reaction. Phosphorus, therefore, readily passes in the form of vapour through animal membranes; but phosphoric acid was also demonstrable in the fluid, when this was well steamed in the water-bath. The lower degrees of oxidation of phosphorous were not demonstrated, but they are in general difficult of demonstration in the presence of phosphorus and phosphoric acid; we can, however, scarcely doubt that the intermediate forms are also present.

Phosphorus behaves in blood, with respect to its diffusion, as it does in water, and Bamberger therefore expected to find the same in experiments on animals. He gave small granules of from 10 to 12 milligrammes of phosphorus daily, and usually observed for the first four or six days, no other phenomena than diminished appetite (a rabbit got even for 13 days 10 milligrammes daily, that is 130 mgrm., before it died).

(To be continued.)

Proceedings of Societies.

ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

THE General Session of this Association was held on Monday and Tuesday, July 20th and 21st.

The Association met on Monday at the Freemasons' Tavern, when, in accordance with the resolution of the Council, the claims of the several candidates for the representation in Parliament of the conjoined Universities of Edinburgh and St. Andrews were to be considered.

On Tuesday some members visited the Church of Hempstead in Essex, where in the family vault lie the remains of Harvey.

The transactions of the Association were ready for distribution on the first day.

The discussion on Monday was the chief business of the Session, and there were about forty members of the society present.

Some preliminary business having been disposed of, the adoption of the report of the Council was moved by Dr. **GREENHALGH** and seconded by Dr. **NICHOLLS**. This report was drawn up on the previous Saturday at a meeting of the Council, at the house of Dr. Richardson, when ten members were present. It declared that the representative of the two Universities of Edinburgh and St. Andrews ought to be a medical man, and recommended Dr. Richardson as candidate.

Dr. **RICHARDSON**, who as president occupied the chair, then addressed the meeting. He said he was not very ambitious of parliamentary life, but he believed in calls, and if selected by the Association he should regard it as a call, and stand as a candidate; at the same time, he would not incur any expense. Those who sent him must defray the legitimate costs, and he would not sanction expending a penny more than was absolutely necessary. As to politics, he would not side with either Mr. Disraeli or Mr. Gladstone. He thought old foundations which had been proved to be good, should be retained in preference to making new ones. He believed the Association, numbering nearly 600 graduates, had the power to return a member if it acted unanimously, and thought that a medical man should be returned.

Dr. **DRYSDALE** regretted not to hear more definite views from Dr. Richardson, especially on the great questions of civil and religious liberty. He had heard at the preceding Council meeting that Dr. Richardson was not prepared to support Mr. Gladstone in the disestablishment of the Irish Church. Now, he could not conscientiously vote for any candidate who supported the establishment of the alien church of the minority in Ireland.

Dr. **SHORTHOUSE** said they wanted a medical man, and had nothing to do with the Irish or any other church.

Dr. **KING** objected to taking into consideration the politics of the candidate. He wanted a representative of medicine.

Dr. **O'CONNOR** said that a medical man, a member of the Association, had issued an address. As he saw him present, he would like to hear his views. He referred to Dr. Prosser James, and begged to inquire whether he was a *bona fide* candidate.

Dr. **PROSSER JAMES** replied that he was a *bona fide* candidate, and having the support of many graduates in all the faculties as well as of political friends, both in and out of Parliament, hoped for success. Unlike the President, upon whose scientific reputation he passed the highest eulogium, he was a party man. He did not think politics could be excluded from such a contest, nor could he admit that they ought to be. He would not detain them by repeating his medical politics, as he had forwarded a statement to every graduate of both Universities. He had hoped for the support of the majority of his medical brethren on the strength of his programme for reform in the profession. At the same time he could not forget that there were other faculties, and he knew he had lost some support by giving too great prominence to medical matters; although he had doctors of divinity and laws, as well as Masters of Arts working for him. He did not believe with the chairman that the Association could return their nominee. Why, they were only 500 or 600, and there were perhaps 5000 members of the University Council. Besides, this Association was not only medical, but was for one University out of two. The sister University was entitled to at least equal respect, and the graduates in the other faculties could not, and ought not to be ignored. No one loved his profession more, or would make greater sacrifices for it; but he could not make all social questions secondary to it. He did not scruple to remind them, that society did not exist for the sake of medical men, but medical men for society. On every general question he was as liberal as on medical ones. Indeed, it was only as a liberal he asked the suffrages of the constituency. As the Irish Church had been mentioned, he might repeat that he thoroughly supported Mr. Gladstone on that question. He thought farther that all churches would be better without State interference, and that it would be a good thing for all States to be untrammelled by any church.

Dr. **Edwards Crisp** thought general politics should not be considered, and suggested that the medical candidate most likely to succeed should be pushed by the Association.

Dr. **Martin** would not support any candidate who would vote against the Irish Church.

Dr. **O'Connor** thought it was too late for Dr. Richardson. The medical graduates could not enforce their views. He said the other candidates ought to be considered, as he did not think the medical ones were either of them likely to succeed. As to Mr. Campbell Swinton, he found that his chairman and vice-chairman were Professors Christison and Shairp, both men most bitterly opposed to the enfranchisement of the medical graduates, and the former of whom opposed all medical reform. He thought, therefore, the Tory candidate had no claim on the profession. Professor Playfair he considered a good candidate, liberal on most questions, and possessing such large support that he believed him very likely to succeed. He, therefore, asked the meeting to support him, and not by division let the enemy of the profession and the Conservative creep in.

Dr. **Rogers** regretted that Dr. Richardson's views were not like his own, advanced Liberal, but would support him.

Dr. **Sedgwick** said many had promised to support Dr. Lyon Playfair under the mistaken notion that he was a medical man.

Dr. **Dudfield** gave an account of the getting up of a requisition. Nearly 200 signatures were gained.

Dr. **Richardson** said he did not come forward sooner lest it should imperil the enfranchisement. He could not consent to taking a wedge out of the constitution by disestablishing the Irish branch of the Church. But for the clergy of that Church we should have had no literature. He then put the report to the meeting.

Dr. **Sedgwick** counted the hands held up, which were 26. The contrary was then put, and as no one held up a hand the motion was declared to be carried.

The meeting then broke up, some of the friends of Dr. Richardson remaining to concert measures on his behalf.

FORFARSHIRE MEDICAL ASSOCIATION.

The tenth annual meeting of this Association was held, on the 19th ult., at Forfar, Dr. Smyth in the chair. The following were present:—Drs. Smith, Steel, Murray, Maclagan, and Alexander, Forfar; Drs. Nimmo, Arrott, Christie, Crockatt, Begg, J. W. Miller, Rorie, Pirie, Petrie, Allan, Steven, and James Duncan, Dundee; Dr. Park, Broughty Ferry; Drs. Lawrence, Johnston, Officer, Watson, and H. Steele, Montrose; Drs. Alexander Guthrie, Mackie, sen., Hammond, J. Guthrie, and Mackie, jun., Brechin; Dr. Grant, Glamis; Dr. Simpson, Marykirk; Dr. P. Heron Watson, Edinburgh; and Dr. Andrew Smith, Staff-surgeon, Aberdeen.

It was decided to present a memorial to the Home Secretary, showing that it would be advantageous if the office of Poor-law Medical Officer were put on the same footing towards the parochial board as that of inspector—namely, the power of removal to be exercised only with the sanction of the Board of Supervision.

It was agreed to hold the next annual meeting in Dundee. Dr. Steel (Forfar) moved the appointment of the following office-bearers, who were unanimously elected:—President, Dr. Arrott (Dundee); Vice-presidents, Drs. Nimmo and Gibson (Dundee); Secretary, Dr. James Duncan (Dundee); Treasurer, Dr. Allan (Dundee); Council: Drs. Christie, Crockatt, Begg, J. W. Miller, Pirie, and Rorie (Dundee); Local Secretaries: Dr. Lawrence (Montrose); Dr. John Guthrie (Brechin); Dr. Alexander (Forfar); and Dr. Dewar (Arbroath.) Dr. Smith, President of the Association, brought forward notes of interesting medical cases. Dr. Lawrence (Montrose) read an exceedingly interesting paper "On Traumatic Cerebral Abscess." A discussion ensued, in which several members present took part. On the motion of Dr. Arrott, the thanks of the meeting were cordially awarded to those gentlemen, and to the President, for his conduct in the chair. The members afterwards met and dined in the County Hotel.

◆

RULES FOR REGISTRATION IN THE SCOTTISH UNIVERSITIES.

1. All Graduates of either of the four Universities may enrol as members of Council of their respective Universities.

2. All persons may also enjoy the privileges of Graduates who, previous to 1861, attended four sessions at any Scottish University, or three at one and one at another University, provided that two of the four sessions were spent in attendance at general classes. Four purely medical sessions will not suffice, and in making a claim for registration under this heading, it is necessary that a record as to years of attendance should be sent to the registrars.

3. All applications must be addressed to the registrar, and accompanied by a post-office order for 20s.

4. All those graduates who have hitherto paid annual subscriptions in lieu of composition fees, must now make up their previous payments to 20s., all such payments being allowed in deduction.

5. Electoral privileges give power to record votes by voting papers, at all University elections, including those for members of Parliament, chancellor, and assessors.

6. The register will be closed on the 1st of October.

◆

Correspondence.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—On Wednesday, the 15th of this month, I called your attention to the partial statement made by your reporter of the proceedings of the General Council of Medical Education and Registration, on Saturday, July 4, on which day Dr. Apjohn brought no less than three separate and distinct charges against my report of the visitation in reference to the examinations in Trinity College Dublin for the Degrees of B.M. and Mag. Chir., held in December, 1867, as being "untrue," which I replied to on the instant before the Council, completely to my vindication, of which your reporter takes no notice. Dr. Apjohn's first charge was that the candidates were recalled after the close of the examination, and the names of the successful and unsuccessful candidates were announced. In explanation, I replied, all the candidates were called in, the names of the successful candidates were announced; what became of the unsuccessful ones? Surely their being paraded before those who were present and their names not called, was equivalent to a public announcement that they had not passed. The second charge was the Professors were the only examiners, by which I made it to be understood that no non-professional examiners not connected with Trinity College were appointed for that duty. *Such was the fact* up to December, 1867, when I visited that institution as a Member of the Irish Branch Council of the General Council of Education and Registration, *but since then* the University has commenced setting its medical house in order, and selected two other examiners in Surgery—Mr. Butcher and Mr. Wharton, from the Fellows of the Royal College of Surgeons in Ireland.

The third charge against my report being "*untrue*" was that the candidates were not tested in writing or dictating prescriptions; again I affirm, *such was the fact when they were examined orally* in the practice of medicine and surgery, and the oral or *viva voce* examinations which my report *specially* referred to, requires to be corrected in all future examinations for the medical and surgical degrees of Trinity College.

From my experience of the last meeting of the Medical Council, the word "*untrue*" is a favourite expression of Dr. Apjohn, and from a Member of the Council (July 1) to whom he used the same expression, he received a reprimand which he most justly merited and will not soon forget.

As the reporter of THE MEDICAL PRESS AND CIRCULAR is silent on this subject, affording me no information for ignoring my reply, I have consequently been obliged to vindicate myself from those most unmerited aspersions of Dr. Apjohn on my report of the examinations for conferring the degrees of B.M. and M.C. of Trinity College Dublin, in December, 1867. As a public journalist you will at once see the justice of inserting this in the columns of the next number of THE MEDICAL PRESS AND CIRCULAR.—I remain, sir, your obedient servant,

WILLIAM HARGRAVE,
Representative of the Royal College of Surgeons in Ireland on the General Medical Council of Registration and Education.

56, Upper Mount-street, Dublin,
July 24, 1868.

MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The questions raised in your columns deserve all the attention of medical men.

It is plain that something must be done. Either the expensive and difficult reform urged by Dr. Andrew Wood and the Medico-Political Association must be effected, or else the easy and inexpensive proposal of Dr. Prosser James must be accepted. The beauty of this latter is that it would bring many other privileges with it.

It would be a reform of the corporations as well as of the Council.

Dr. Ashe is too trenchant by far, and when he uses the word "hoodwink," does injustice. For my part, I like the indirect plan, and thank our excellent representative, Dr. Paget, for taking it up in the Council. Although the plan had been fully explained by Dr. Prosser James, it would, perhaps, not have made the sensation it has, had not Dr. Paget leaned to it in his speech. Perhaps for that reason he should have given the author the praise due to him. This much I would urge—let the other universities and corporations be as liberal as Cambridge, and the indirect method would be fully established.

Dr. Ashe talks of the Senate here as if it were controlled by a committee.

No such thing; it is open and fair. Nothing can be done without the consent of the Senate, which includes all M.A.'s, and all doctors who keep their names on the books. Like Dr. Williams, in his letter in your last impression, I think the more medical men in the House of Commons the better; and I, too, wish Dr. Prosser James and his plan of indirect representation success.—I am, &c.,

CANTAB.

ON DINING.

"Ding goes the dinner-bell,
Tingle, ding dong,
Pray what can the matter be—
Dinner's so long.
Five minutes more to wait
For turkey and ham,
The juice of the ruddy grape
Is better nor jam."—*Old Song.*

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I agree with "Sanitas," dinner *a la mode* is verily dinner *a la* ———. Ah! I won't say it, but it verily is. I like to dine, however—who doesn't? A great wit, you remember—that doctor who said, "come, let us walk down Fleet-street," was asked his opinion on dining. "I like to dine," was his answer. He would hardly stand a "bolting" process of two hours' duration though, at a temperature of 212° in the shade, and "high pressure" all round. The term "dinner" ought to become obsolete. It is a barbarous, luxurious, luscious term, whose very sound as it strikes the tympanii, causes a tickle in the "inside," from long habit. I would humbly suggest that the term "compensatory process" be substituted, and that the "compensatory" should be availed of just as the promptings of nature suggest. "Man is the only animal that dines by rule," thanks to, well, say civilization; but we know there are "parties" so civilized by the process as not to be able to *stand* it to the end, and who become *prostrate* under its application.

It will be difficult, no doubt, to upset the universal dinner-table. There are, even in our very midst, thousands of persons, exclusive of Aldermen and T. C.'s., who would cling to dining table legs to the very death, were a bold attempt made to disjoint them.

"A meat tea," as "Sanitas" wisely suggests, repeated *ad lib.*, I meekly respond, would do very well to begin with; and no evening coats with morning continuations. "Crusty" old bachelor Perkins, who reads as I write, snamblingly adds—But who will commence this reform movement?

"Mr. Chairman"—Mr. Editor I mean, "I move that 'Sanitas,' whose mighty intellect and brilliant pen mooted the great question 'On Dining,' *do* give a 'compensatory process,' and thereby practically illustrate the point he has so sumptuously, (no! not sumptuously, there is too much of the pungence of the dinner-table about that term), so eloquently, yes, so eloquently, seeks to reform.". Please second this, and believe me to be, very faithfully yours,

SAINT PANCRAS, JR.

P.S.—Do you think this will "bring out" "Sanitas," as I like a good dinner "on the Strand."

THE CONTAGIOUS DISEASES ACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Ever since about this time last year, I have watched with anxiety the proceedings of the different meetings held in connection with the Prevention of Contagious Diseases Act, in order to have its operations extended to the civil population, and I am sorry to see that nothing as yet has been proposed for the protection of these unfortunate women, of whom so much is said, and to whom so much blame is attached, without considering that they are the first victims of the immorality of men.

As it appears that it is intended to submit to the English Parliament, plans devised according to the French system, and as I think it right that the subject should be looked at in all its bearings, I beg to submit to the impartial consideration of your readers, and especially of the gentlemen forming the Committee, an extract translated from a chapter written on the same subject by Jules Janin—the French Charles Dickens.

"At the top of the Rue St. Jacques there is an hospital, but an hospital wanting both pity and respect. The surgeon himself despises his patients. The diseases there assume every kind of horrible forms, and names which are only hinted at in a low voice; it is more a prison than an hospital. The police is the queen and the mistress of it. It is not the Christian Charity but the Prefect of Police who opens the doors of this fatal asylum.

"I have seen in it young men, pale and livid, with a skin of an undescribable colour, and deprived of their senses and reason. Next to them were fathers of families, in mourning for their wives and children, whose death they had been the cause.

"A little further were some horrid old men, kept by the Faculty as curious specimens, and shown to strangers as being more horrible than any that they had in their own country—worthy subject of pride!

"I was going away when some one told me that the hospital was divided into two parts, and that upstairs were the women. 'Do you not want to see the women, sir,' they said, as if they were much more worthy to be looked at. In going up I met nurses infected by the babies they had taken to nurse. Some poor young country girls weeping, knowing nothing about their disease, and hiding their faces with their coarse apron.

"At the door of a ward was a young innocent-looking woman, the miserable victim of her husband. She was there, immovable, like a statue, waiting for a place in a bed by the side of some old prostitute. What! the woman nursing a baby. What! the young girl who gives herself up to her lover or her husband, they also are contaminated by this horrible disease. Poor women, hundred times more to be pitied than these other inmates downstairs.

"I entered a large room, there I found many women, some old habituées, who make the hospital their homes, and turn it into a house of pleasure and of rest; they were all laughing and playing at different games. Some were ornamenting themselves with a veil, or some bright morning gown. The youngest, half dressed, were comparing their youth and their beauty; others were uttering fearful oaths, or singing with a harsh voice some drinking songs of debauchery. The greatest part of these women were still young and handsome. Poor, miserable women! handsome enough to be still handsome in such a place, unfeeling enough to laugh and sing. They might have been the pride of a young man, the honour of a happy home, the companion of a strong man, and his help in his old age; but no. At the instigation of men they have given away all that, they have sold themselves for nothing. No! not for nothing; but for ulcers and diseases, all the precious gifts which they had received from God—comeliness, youth, cheerfulness, health, and happiness, they have lost all. Oh, it is horrible! horrible!

"At a given signal, all the games ceased, and a mournful silence succeeded to all the noise. Every woman fell in, and all walked in a line to the place where the surgeon was waiting for them. It was a small, low room, lighted by a single window, opening at the back of the house, the walls of it are of a dirty greenish hue, strangely ornamented with obscene figures, drawn either by the patients or the students. On a bedstead is a small paillasse, covered with a black cloth; by the side of the bed were, here and there, every kind of cutting instruments, and a small stove where several pieces of iron are getting red hot.

"Around the bed were several old women, who by their services had deserved to be present at the show, and on the only chair in the room sat the elegant operator, talking with his pupils about actresses and the news of the day. I joined these young rivals of Esculapius, and I may say, that I was the only one there moved and attentive.

"Through the half-open door, I was looking at all these women so thinly dressed, and waiting for their turn, with an impatience as if they had been at the door of an opera-house. Amongst them, were charming, youthful faces, with a melancholy smile on their lips, others with strong, marked features, black eyes and hair, it was a strange and varied assemblage of beauty.

"At the name of Henriette, I saw coming forward a young, handsome girl, keeping her head erect and a disdainful look in her eyes. She threw herself on the bed—everybody was silent; the operator took some curbed scissors and began cutting in the sound flesh.

"When overcome by the pain, the poor girl either moved, or uttered a faint moan, she was answered by words of anger and contempt; as for myself, I was admiring so much beauty reduced to such a degradation! When the operator had done with the scissors, he took the red iron, and burned, without any signs either of feeling or pity, all these bleeding sores, occasionally looking at his work as a young painter looks at his first landscape; then, with a harsh, unfeeling voice, he cried: get away you wretch and do not let me see you here again.

"She rose, pale, suffering, walking with difficulty, and disappeared.

"After a while, when I left the hospital, there, outside of the gate, on a heap of stones, sat two women, one was Henriette, the other the young married woman whose decency and grief had struck me. Both cured, as it had been said, both had been put out of the hospital, half-naked and dying with cold—Henriette without a home, the other not daring to go to her own. Henriette went back to the licensed house, where all the police regulations had not been able to save her from the infection, and likely to fall the victim of it again.

"At the same instant, several other girls came out; they were all laughing and talking aloud. At seeing them so gay, nobody would have imagined what these unfortunate girls had suffered.

"Touched with pity, and perhaps curious to see the house of the poor married woman, I took a cab, and asked her to get in.

"She was in such a state of mind as not to hear me at first; at last, she said: 'Oh, sir! my husband lives very far from this, I asked him to come and take me out of this miserable house, but he did not come; and without you I might have died of cold and shame.' Then, she got into the cab, but the nearer we came to her house, the more sad and anxious she became.

"'What is the matter?' said I. 'Why do you tremble so.' 'Alas,' she said, 'my husband! how will he receive me? How will he forgive the wrong he did to me?' and she looked so pale and livid. At last we arrived at the house. We went upstairs and knocked at a door on the second floor. A coarse voice said 'Come in.' I went in first. A man surrounded with boxes and papers stood up. He looked at his wife as if he had seen her a few hours before, without saying a word either of kindness or regret. Oh, the brutal man! He had red eyes; his hair fell flat on his neck and face, which was covered with large pustules. . . . .

"'Oh! miserable woman,' said I, 'what are you coming here for? you would be better where you come from.' She began to cry, and looked at me as to say, 'I know what awaits me here. Before long I will be again where you found me this evening.' Poor woman! Poor woman! who will protect and defend you?"

Now, sir, I think it is evident from the foregoing article, that the French themselves are of opinion that something is wanted besides this infamous police system.

Judging from the measures either proposed or already in activity in this country, one would say that everything is done to induce every class of men to addict themselves to their passions without impunity. If inquiries are made, it will be found that the most substantial support of these unfortunate women comes from married men, and although it is easy to guess what amount of misery it must inflict on the families of these men, yet nothing is proposed to counteract it. Perhaps, if special constables were appointed to do duty about the dwellings of these unfortunate women—they are generally congregated in some few streets—so it would not be difficult to have them watched, this simple measure would deter many men from frequenting these houses, in fear of being known or remarked.

At all events, it is to be hoped that the Committee will recommend such measures as will protect these unfortunate women, and prevent them, if possible, becoming the miserable subjects of the disgusting scenes so powerfully described by Jules Janin.—I have the honour, &c., E. L.

POISONOUS EFFECTS OF "CYTISUS LABURNUM."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As Physician to the Cashel Workhouse, I was lately called upon to treat a number of cases suffering from the poisonous effects of the "Cytisus Laburnum," which I send you an account of, with a few practical remarks, that may be useful to other medical men.

On the evening of the 9th instant, sixteen female school children, inmates of the Workhouse, ate a quantity of the laburnum-seeds. The ages ranged from three to twelve years; they were healthy children, and in good condition. None of them could tell how much they ate.

The symptoms that presented themselves were vomiting, anxiety, quick and weak pulse, pain in epigastric region, twitchings of the muscles of the face, eyes rolling, surface of the body cold, tendency to sleep, and drowsiness. All these symptoms did not appear in each case, though some did. I have therefore grouped them, as it answers my purpose at present.

I lost no time in getting the children away from confusion, and that excitement that naturally runs through numbers when they hear of a number of children having been suddenly poisoned. I had them sent to the infirmary at once, and doing all I could to allay their anxiety, treated them all with emetics. I selected mustard; it answered my purpose well. In some of the cases the aromatic spirits of ammonia, held to the nose for some time, was very grateful.

They all recovered. I kept them on milk-diet for two days, and discharged them from hospital quite well on the 11th inst., with the exception of one child I retained, who had slight ulcers on the arm.

The important points to be kept in view in such cases are—firstly, to remove as soon as possible the poisonous matter which is causing embarrassment of the system; and secondly, closely to watch any symptoms that may index the approach of the cerebro-spinal system becoming affected; and, whilst watching, all anxiety should as much as possible be allayed, for the use of the physician, as well as his patients and others, that his judgment may be cool and calm, and that all perturbing emotions and influences may be put aside. Unfortunately, in all cases this cannot be accomplished, for you will sometimes find or meet with an obstinate parent, or other person, who will think they have a right to interfere, and as you have not time to teach them of their ignorance, you must endeavour to mind them as little as possible, and not allow your attention to be taken off your cases. Steady, close attention is invaluable in such cases, and well the physician is repaid when he sees his little patients recovering from the deleterious influences of what he dreads will destroy them; and whilst closely watching, light increases, which assists him in comforting and cheering, as well as having relieved.

Here is a group of cases which show the necessity and the economy of attending to the general health and strength of children as they grow up, when we find them subject to such accidents and influences (often epidemic) that are liable to seize upon them in numbers.—I remain, sir, your obedient servant,

James Graham, M.D.

◆

Medical News.

Royal College of Surgeons of England.—The following gentlemen having undergone the necessary examinations for the diploma were admitted members of the College at a meeting of the Court of Examiners on the 23rd inst., viz.:—Messrs Brandford Edwards, L.R.C.P., Ipswich; J. D. Mason, Lewisham, Kent; T. J. Gittins, Barbadoes, West Indies; Francis Lett, Woolwich; Edward Colson, Great Hormead, near Buntingford; Richard Banks, Cockermouth, Cumberland; and C. E. Wing, Bury St. Edmunds, students of Guy's Hospital; Herbert Boyd, St. John's, New Brunswick, of St. Mary's Hospital; Leonard Smith, Cambridge-street, of St. George's Hospital; William Morris, Birmingham, of the London Hospital; M. W. W. Chorley, Leeds, of the Leeds School of Medicine; David Brown, Dublin, of the Dublin and Belfast Schools; Daniel Ainley, Halifax, of St. Bartholomew's Hospital; W. J. Scott, Cape of Good Hope, of University College Hospital; Robert Patrick, Bolton, Lancashire, of the Manchester Royal School of Medicine and Surgery; Tom Bates, L.R.C.P., Edin., Worcester, of Paris and Glasgow; and G. S. Walker, Islip, Oxon, of St. George's Hospital. It is stated that seven out of the twenty-four candidates failed to acquit themselves to the satisfaction of the Court, and were referred to their hospital studies for a period of six months.

Royal College of Physicians of London.—The following is the list of members nominated by the Council for election as Fellows (July 30th, 1868):—William Ogle, M.D., Cantab., Derby; Charles Alexander Lockhart Robertson, M.D., Cantab., County Asylum, Hayward's Heath; Thomas Harrington Tuke, M.D. St. Andrews, Manor-house, Chiswick; John Deakin Heaton, M.D. Lond., Claremount, Leeds; John Edward Morgan, M.D. Oxon, St. Peter's-square, Manchester; Walter Moxon, M.D. Lond., Finsbury-circus; John Hughlings Jackson, M.D. St. Andrews, Bedford-place, Russell-square; Reginald Edward Thompson, M.B. Cantab., South-street, Park-lane; and Edmund Symes Thompson, M.D. Lond., Upper George-street, Portman-square.

College of Physicians (London).—The following is a list of office-bearers proposed for election on the 30th inst.:—Censors: Drs. Risdon Bennett, Wegg, Quain, and Barclay. Treasurer: Dr. F. J. Farre. Registrar: Dr. Pitman. Librarian: Dr. Munk. Members of Council: Dr. Handfield Jones (in the room of Dr. F. J. Farre), Dr. Walshe (in the room of Dr. J. R. Bennett). Examiners—Anatomy and Physiology: Drs. J. W. Ogle and Hyde Salter. Chemistry, Materia Medica, and Practical Pharmacy: Drs. Sieveking and Marcet. Midwifery and the Diseases peculiar to Women: Drs. C. B. Brown and Priestley. Medical Anatomy and the Principles and Practice of Medicine: Drs. Owen Rees and E. L. Birkett. Surgical Anatomy and the Principles and Practice of Surgery: Messrs. J. Birkett and T. Holmes. Curators of the Museum: Drs. Hamilton Roe, F. J. Farre, W. Wegg, and F. Sibson.

The Public Health.—The returns of the Registrar-General are again beginning to excite more interest. We have not been able for the last week or two to make the favourable remarks on the public health which had become almost routine work. That our readers might know the exact facts, we have consequently reprinted the more important items of the weekly returns. We continue this plan in the more important return of the last week:—In the week that ended on Saturday, July 18, 4222 births and 3483 deaths were registered in London and in 13 other large towns of the United Kingdom. The annual rate of mortality was 28 per 1000 persons living. The annual rate of mortality last week was 27 per 1000 in London, 25 in Edinburgh, and 19 in Dublin; 22 in Bristol, 28 in Birmingham, 33 in Liverpool, 39 in Manchester, 28 in Salford, 38 in Sheffield, 30 in Bradford, 28 in Leeds, 24 in Hull, 30 in Newcastle-upon-Tyne, and 28 in Glasgow. The rate in Vienna was 26 per 1000 during the week ending the 11th inst., when the mean temperature was 1·5 Fahrenheit lower than in the same week in London, where the rate was 25. Under the influence of the present sultry heat and drought the annual rate of mortality in the 14 large towns of the United Kingdom has, week by week, steadily increased from 22 per 1000 in the beginning of June to 28 last week. The increase has been greatest in London, Liverpool. Manchester, Birmingham, and Sheffield, and has been almost entirely due to the fatal prevalence of summer diarrhœa, principally infantile. Of the death-rates per 1000 from all causes, 11 were referred to diarrhœa in Manchester and Salford, 7 in Sheffield, Leeds, and Liverpool, 6 in London, and 5 in Birmingham. The deaths registered in London during the week were 1642. It was the twenty-ninth week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1458. The deaths in the present return exceed by 184 the estimated amount, and are more by 137 than the number recorded in the preceding week. The deaths from zymotic diseases were 677, the corrected average number being 521. 87 deaths by choleraic diarrhœa or cholera were registered in the week, 29 being children under four years of age. 7 cases in adults appear to be ordinary instances of summer cholera; another adult is returned as having died of "rheumatic fever (13 days), and choleraic diarrhœa (10 days)." 340 persons died of diarrhœa, and of that number 19 were adults. It must not be assumed that the mortality from diarrhœa or summer cholera is higher in London than it is in Continental towns. The reverse will be found generally to be the case. At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·848 in. The barometrical reading decreased from 29·96 in. at the beginning of the week to 29·85 in. by 3 P.M. on Monday, July 13; increased to 29·93 in. by 9 A.M. on Tuesday, July 14; decreased to 29·75 in. by 3 P.M. on Wednesday, July 15; increased to 29·89 in. by 9 P.M. on Friday July 17, and was 29·83 in. at the end of the week. The mean temperature of the air in the week was 70·7 deg., which is 8·5 deg. above the average of the same week in 50 years (as determined by Mr. Glaisher). The highest day temperature was 92 deg., on Thursday, July 16. The lowest night temperature was 52·7 deg., on Tuesday, July 14. The entire range of temperature in the week was, therefore, 39·3 deg. The *maximum* temperature of the air observed on Thursday, July 16—viz., 92 deg., is a higher value than has been recorded since July 18, 1859, when the *maximum* temperature was 93 deg., and the mean temperature (75·9 deg.) is higher than all other mean daily temperatures as far back as the 16th of June, 1858, when 76·9 deg. was obtained. The mean of the highest temperatures of the water of the Thames was 68·5 deg.; that of the lowest was 67·9 deg. The difference between the mean dew point temperature and air temperature was 12·9 deg. The mean degree of humidity of the air was 64, complete saturation being represented by 100. Rain fell on Sunday and Monday to the amount of 0·70 in. The general direction of the wind was N.E. and S.W. Electricity was shown on every day of the week, except Monday and Thursday. Ozone was observed on Wednesday and Thursday. According to a return furnished by the engineer of the Metropolitan Board of Works the daily average quantity of sewage pumped into the River Thames at the Southern Outfall Works, Crossness, was 48,319,036 gallons, or 219,536 cubic metres, equivalent to about as many tons by weight.

Overdose of Laudanum.—A very melancholy event occurred last week at Congleton. Mr. Henry Schofield, surgeon, having a considerable practice in that town, being much afflicted with tooth-ache, has been in the habit of taking laudanum to mitigate the pain. Yesterday he took a larger dose than usual, and symptoms of poisoning were immediately perceived. Medical aid was obtained as quickly as possible, and every effort made to eject the liquid, but without success. Mr. Schofield died in great agony. He was highly respected in Congleton. He was married, but has left no family.

OF THE
UNIVERSITIES OF EDINBURGH AND ST. ANDREWS.

GENTLEMEN,—With the support of many influential Political and Professional friends, I offer myself as a Candidate for the honour of representing you in Parliament, and ask your support at the next election.

I have always advocated an increase in the number of University Constituencies.

When the Scotch Reform Bill was proposed, I spent much time in urging upon those who might influence it, the Claims of the Scottish Universities to at least one Member each.

When two Members were offered between the four Universities, I collected and circulated statistics showing that this would give a much less prportionate representation than that enjoyed by the Universities of Oxford, Cambridge, and Dublin.

More recently, when it was proposed to give only one Member between the four Universities, I organized an active opposition to this unfair reduction.

At a later period when three extra Members were placed by the Committee of the House of Commons at the disposal of Government, I pointed out how just it would be to give two of them to the Scottish Universities, and thus provide one Member for each of those important seats of learning.

As a Doctor of Medicine of one of the Universities I aspire to represent, I retain a lively interest in their welfare.

My plan of Medical Reform has received the emphatic approval of some of the most distinguished Practitioners of the day, and if carried out would tend to enhance the value of our University Degrees.

As a resident in London throughout the year, I should be able to devote much time to Parliamentary duties, and it would always give me pleasure to confer with any of my constituents,

I am,
Gentlemen,
Your faithful servant,
PROSSER JAMES.

UNIVERSITIES
OF
EDINBURGH AND ST. ANDREWS.

ELECTION OF A MEMBER OF PARLIAMENT.

THE Committee for promoting the Election of DR. PROSSER JAMES, will feel greatly obliged to all who may kindly intimate their intention of supporting him, or their willingness to have their names added to his Committee.

The Electoral Committee consists of members of either General Council, and gentlemen qualified to register as such, who support Dr. Prosser James.

All Graduates of either of the Universities, and all Students who prior to August, 1861, attended four Sessions in either of the Universities, or three Sessions at either and one Session at any other Scottish University, two of such Sessions having been in the course of study in the Faculty of Arts, are qualified to register as life members of General Council before 1st October, 1868, on payment of a composition fee of £1.

The *Medical* Committee consists of Members of the Profession (of all shades of politics) who, whether Electors or not, desire to see the medical element in the House of Commons increased, and who consider Dr. Prosser James a suitable Candidate.

The Medical Committee will be pleased to receive suggestions or criticisms on the plan of Medical Reform proposed by Dr. Prosser James, from any one interested in the subject.

The *General* Committee includes the above, as well as other supporters of Dr. Prosser James.

Communications may be addressed to either of the undersigned (Honorary Local Secretaries to the different Committees):—

J. HOWARD HINTON, A.M., Reading.
A. MORTON BROWN, LL.D. Cheltenham.
GEO. W. BALFOUR, M.D., 18, Lynedoch-place, Edinburgh.
CHARLES DRYSDALE, M.D., 99, Southampton-row, London.
R. P. B. TAAFFE, M.D. and M.S.Lond., Old Steyne, Brighton.
R. L. JOHNSON, 61, Charrington-street, London.
C. A. GORDON, C.B., M.D., Deputy Insp. Gen., Army Hospitals, Portsmouth.
PETER D. MUIR, M.D.Edin., Wombwell, Barnsley, Yorks.
GEORGE DAWSON, A.M., Birmingham.
R. E. B. HORNIBLOW, M.D.Edin., Leamington.
W. R. BAXTER, LL.D., Emsworth.
ALBERT HIND, Gravesend.
THOS. SIMPSON, Coggeshall.
R. CORNMELL, 16, Upper Phillimore Gardens, Kensington.
A. S. MYRTLE, M.D.Edin., Harrogate.
A. T. MACGOWAN, 136, Gower-street, London, W.C.
J. D. ADAMS, M.D., Martock.
A. H. JACOB, M.D., T.C.D., F.R.C.S.I., 23, Ely-place, Dublin.

Or simply to the COMMITTEE, 18, Dover-street, Piccadilly, W.

THE MEDICAL PROFESSION.

THE ALBERT LIFE ASSURANCE COMPANY. Established 1838—Annual Income £350,000, accepting healthy and invalid lives, is prepared to enter into special and liberal arrangements with members of the Medical Profession acting as private Agents of the Company.—Apply to the Secretary, FRANK EASUM, at the Chief Office, 7 Waterloo-place, Pall-Mall, London.

NATIONAL ASSURANCE COMPANY
OF IRELAND,

ESTABLISHED 1822, and Incorporated by Royal Charter,
For Fire, Life, and Marine Insurance, and granting Annuities.
PRINCIPAL OFFICE:
3, COLLEGE GREEN, DUBLIN.
Capital One Million.
DIRECTORS—

DIGGS LA TOUCHE—CHARLES LESLIE—LUKE JOHN M'DONNELL—RICHARD MANDERS—HUGH O'CONNOR—THOMAS PIM—GEORGE PIM—PATRICK SWEETMAN—HENRY THOMPSON—RICHARD WILLIAMSON.

FIRE DEPARTMENT.

THE Directors call the attention of the Public to the new Table of Life Rates, in which a considerable reduction has been made, particularly in the younger lives for whole term, affording to the Assured the utmost advantage consistent with security.

A Quinquennial, instead of a Septennial, division of Bonus has been adopted; the first Bonus averaged Two per Cent. per Annum on the Sum Insured, and the result of the Actuary's Investigation for the Five Years ended 31st December, 1862, is still more favourable, as shown by the following Example:—

Date of Policy.	Age.	Amount Insured.	Annual Premium.	Bonus Added Dec. 1857.	Bonus Added Dec. 1862.	Total.
		£	£ s. d.	£	£	£
1851	58	500	32 5 0	86	96	182
1852	50	3000	136 2 6	407	416	823
1853	40	1000	32 18 4	97	107	204
1854	55	600	32 11 0	50	90	140
1855	57	500	29 9 2	29	77	106

At the option of the Assured the Bonus may be commuted for a reduction in the Annual Premium, or a payment in money.

The Assured are allowed, in time of peace, to pass from one port in Europe to another, in steam or other decked vessels; and residence in other parts of the World allowed on very moderate terms.

No charge for Life Policy, Stamps, or Entrance Money. Age admitted at any time, on satisfactory proof of same being furnished. A liberal return of premium allowed for surrender of Life Policies, on which Four Years' premiums have been paid. Loans granted on Life Policies to the amount of their surrender value. Thirty Days allowed for renewal of Life Policies.

FIRE INSURANCES at the Lowest Rates. Fifteen days of grace allowed for payment of Fire Premiums.

MARINE INSURANCES at current rates of the Day.

In addition tc security, not exceeded by any similar institution in the empire, the utmost facility is afforded in transacting Insurance business, from the fact of the Head Office being in Dublin, and the daily attendance of a Commitee of Directors for the purpose.

By Order, JOSEPH TODHUNTER, Secretary.

The business of this Company is restricted to Ireland.

SIX POUNDS PER WEEK

while laid up by injury, and
£1000 IN CASE OF DEATH
caused by accident of any kind,
May be secured by an annual payment of from £3 to £6, 5s.
TO THE
RAILWAY PASSENGERS ASSURANCE COMPANY,

For particulars apply to the Clerks at the Railway Stations, to the Local Agents, or at the offices,

64, CORNHILL, AND 10, REGENT-STREET,
W. J. VIAN, Secretary.

FIELD'S "WHITE PARAFFINE" SOAP

in tablets 8d. and 1s., is exquisitely perfumed, and imparts a grateful softness and suppleness to the hand. It is especially adapted for warm weather as it exerts a cooling influence on the skin peculiar to itself. See name on each tablet and wrapper.

Wholesale—

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION: THEIR DIAGNOSIS AND TREATMENT.

By S. SCOTT ALISON, M.D. Edin.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

No. IV.

With these local affections of the upper air-tube apparatus there have been associated, in a large proportion of cases simulating pulmonary consumption, certain morbid conditions of the whole system. The scrofulous, the syphilitic, the gouty, the hysterical, the anæmic, and the scorbutic conditions have been found in many cases.

In examples of enlarged tonsils the scrofulous taint has been conspicuous, and in such cases there have often been associated a full state of the soft parts at the angles of the jaw, enlarged cervical glands, a thickness and indistinctness of speech, some dulness of hearing, and a certain amount of stupidity of expression. The scrofulous cachexia, associated with simulated pulmonary consumption, has frequently presented the local manifestations of humpback, curved spine, and the prominent sternum found in the pigeon-breasted.

Cases of throat disease associated with the humpback and the pigeon-breast have often perplexed me, but I have most generally found reason to believe that no tubercle of the lung had ever existed. It has usually been obvious, after long observation, that the cough, even the hæmoptysis, and the difficulty of respiration, were due to tracheal and bronchitic congestion, together with that impediment to respiration and to the circulation of the blood necessarily incident to the deformed, and the compressing conformation of the thorax.

The syphilitic taint has prevailed in cases of atrophied or obliterated uvulæ, wasted velum palati, sometimes perforated with foramina, of hoarse and discordant voice, general deterioration of health, and copper-coloured spots upon the integument of the chest, in young men and middle-aged females.

The gouty taint has shown itself in connection with [illegible] glandules of the pharynx, and conjoined with rather free secretion of yellow or green sputum. Eczematous and herpetic eruptions of the skin have marked these cases, as have also arthritic complications, and an excessive amount of lithic acid in the urine.

The hysterical or quasi-hysterical condition has evinced itself chiefly in connection with young persons, not always females, suffering from tracheal congestion and narrowing of the trachea, marked by some occasional dyspnœa, varying hoarseness of voice, and loud snapping and barking and shrilling cough, accompanied with only very little sputum. The patients have been weakly and delicate, excitable in mind as well as body. Constipation and limpid urine have frequently marked these cases.

Aphonia, dependent upon partial or complete paralysis of the muscles of the larynx, has been conspicuous in the hysterical, but with improving general health and with local stimulation, the voice has generally been restored, sometimes gradually, sometimes suddenly.

The anæmic state has been very commonly observed associated with rough conditions of the pharynx, scanty sputum, pallid lips and cheeks, and velum palati, venous thrill and murmur, systolic murmur at base of heart, palpitation of that organ, œdematous feet, red, polished tongue, gastric irritation and vomiting, and scanty, irregular, or arrested menstruation. The anæmic state has, in a large proportion of cases of simulated pulmonary consumption, been associated, not only with internal morbid conditions of the upper or cervical part of the air-tube apparatus, but it has been conjoined with an enlarged and flabby state of the thyroid body in females. This has formed, as it were, a cushion, placed pretty well round the entire throat, most prominent in front, but in no inconsiderable proportion in the lateral regions. In many cases the swelling has been uniformly soft, but in some it has presented comparatively firm nodules, chiefly in front. Such examples of associated enlarged thyroid body have come from all parts of England, but most have come from the Midland Counties. One example came from Aberdeen, in Scotland.

We recognise the anæmic condition by the pallor of the surface of the body, the lips, soft palate; the conjunctivæ of the eyes; thrilling and murmuring or hissing in the veins of the neck, and by gentle blowing at the base of the heart. But we are not to conclude that anæmia is not present because we find no murmur, or hissing, or humming in the neck, for anæmia, to a great degree, may hold when these signs are absent. The pallid lip and velum palati, and conjunctivæ over-glistening, alone may be ascepted as evidence of this condition. The venous murmur in the neck, and the basic systolic blowing of the heart are more especially found in the young and excitable with active hearts, conducing to rapid currents of blood, while in the older and more passive patients, with feeble, inactive, flabby or fatty hearts, conducing to slow currents of blood, an equally great amount of anæmia is seldom signalised by these adventitious sounds. We must, therefore, not conclude, because an elderly pallid female, with slow heart, does not present the venous murmur, that she is not anæmic, or withhold suitable constitutional treatment.

Taken all in all, in cases of doubtful pulmonary consumption, marked by throat symptoms and signs, I regard the presence of the venous murmur and basic blowing as a weight in the balance—it may be a small one—in favour of the patient, for I have not found this sign to prevail markedly—*i.e.*, with marked frequency, in well-ascertained cases of pulmonary consumption.

I have to-day (July 4th) examined, at the Brompton Hospital, sixteen of my female patients, all that were in the wards at the time, with a view to the discovery of venous murmur. I have found only two patients presenting the venous murmur out of ten suffering from pulmonary consumption in its second and third stages. Out of six patients not tubercular, I find four who present the venous murmur well developed. Five of these non-tubercular patients suffer from various moderate disorders of the upper air-tube apparatus. The sixth suffers from obstinate hæmoptysis, and ulcer or malignant disease of the stomach, marked by thorough intolerance of food on the part of the stomach, necessitating the daily employment of Liebig's extract of meat by enema. Two of the patients suffering from disorder of the throat and anæmia present enlargement of the thyroid body. Two patients with pulmonary consumption, in its third stage, offer the thyroid body also enlarged, one very voluminous reaching nearly round the entire neck, and mounting to the vicinity of the lower jaw.

These examples of venous murmur out of five patients suffering mainly from throat affection, give the percentage of 60; while two examples of venous murmur, out of ten patients suffering from pulmonary consumption in the second and third stages, give the percentage of 20 only.

The comparative absence of anæmic signs in pulmonary consumption, which I have ascertained, coincides with another fact which I made out many years ago when I was a student of King's College Hospital—viz., that the blood of the consumptive, as proved by analysis, is, in most cases, unusually rich in red globules, and super-abounding in fibrin and albumen. The patients whose blood was examined were advanced in phthisis; the conjoined inflammatory affections of course would increase the fibrin.

Another morbid condition of the system, but more particularly applying to the blood, viz.—the scorbutic or scurvy state, is sometimes associated with these local disorders, simulating pulmonary consumption. This state is found in cases marked by general deterioration of the health, emaciation, purplish state of the surface and local hæmorrhages. This condition has more generally been found in cases marked by hæmoptysis, and has prevailed in sailors and in young persons who have been utterly neglected in respect of diet as well as of pure air and cleanliness. In such cases the blood is more than usually liquid, from a deficiency of fibrin and of coagulability. The catamenia in these examples has usually been copious.

When such constitutional conditions are associated with disorders of the upper air-tube apparatus simulating pulmonary consumption, I have observed a fixedness of the local disease, more particularly when the general conditions have not early met with special treatment. On the other hand, when the local treatment has been reinforced by remedial measures addressed to the special general state, the relief of the patient has, for the most part, been early and very satisfactory. This offers an excellent practical reason for the physician, in all cases, to make himself acquainted with the general habit of the patient to be gleaned by his aspect, and by his individual and family history. Such a knowledge and such an inquiry are more particularly imperative in obstinate cases.

It need not be added that local means in cases associated with such general conditions as have been above referred to, demand co-operation from the general treatment indicated by the special associated state.

PURPURIC FEVER.

By JOHN H. BENSON, M.B., L.K. & Q.C.P.I., L.R.C.S.I.,
ASSISTANT-PHYSICIAN TO THE CITY OF DUBLIN HOSPITAL.

The subject of purpuric fever still continues to excite much interest among the profession, owing to its comparative novelty in these countries, to its usually intractable course, to the high rate of mortality which attends it, and to the difference of opinion as to its nature and origin.

In The Medical Press and Circular for April 24th, 1867, I published a case of this disease, with the results of the post-mortem examination. It was found on that occasion that there was not the least trace of inflammation of the membranes of the brain or spinal cord—neither capillary congestion, lymph, nor pus.

Early in this year I had the honour of laying before the Surgical Society of Ireland another case of the same disease, accompanied with cerebro-spinal meningitis, which appeared in the numbers for Jan. 22nd and 29th of The Medical Press and Circular. In my observations upon that case I expressed myself strongly opposed to the opinion that the disease in question was primarily or essentially a cerebro-spinal meningitis, or by any means necessarily accompanied with that inflammation, although they were frequently found associated together, as in the case then before the Society.

Since that time two cases have occurred in my practice at the City of Dublin Hospital, of which the post-mortem examinations remarkably corroborate my view—the one by the total absence of the inflammation, the other by a remarkable condition of the blood, which affords a strong presumption that there was something of more serious import than mere inflammation.

I will briefly narrate the most prominent features of the cases.

F. W., æt. 26, an Englishman, had resided for some years in Ireland as coachman to a gentleman living in one of the best suburban roads of this city.

On Saturday, May 23rd, he felt indisposed, but notwithstanding that he went through his business as usual.

On Sunday he felt considerably depressed and ill, and on Monday he was unable to rise, and was brought to the City of Dublin Hospital.

When put to bed there he was found to be in a state bordering on collapse. The pulse at the wrist was imperceptible, and the first sound at the apex of the heart somewhat diminished. His face was pale, the surface of his body cold, his lips were quivering, some subsultus was apparent in the flexors of the forearm; his eyes had a wild and restless expression, the pupils were natural, but not obedient to the stimulus of light; there was a peculiar redness of the conjunctivæ, and some left internal strabismus; the tongue was slightly furred, but not tremulous; questions were answered hurriedly, but intelligently; respiration was natural; sometimes he complained of pain in the head, at other times he denied its existence. When allowed to rest for a few moments he rapidly lapsed into a semi-comatose state, when his respiration became embarrassed and stertorous.

A sinapism was applied to the precordia, and hot jars to his feet, and an enema of diffusible stimulants and beef-tea was ordered to be administered every second hour, as he refused to take anything by mouth.

Three P.M.—Pulse 80, tolerably regular, but weak and small; subsultus less; temperature more normal; he would answer questions, and when roused would now take medicines by mouth.

Six P.M.—Surface again cold and damp, with a cold, clammy sweat. Pulse of the same frequency as at three o'clock, but weaker, and more irregular. Respiration was of a peculiar blowing character, but showed no tendency to the ascending and descending form. Hot jars were ordered to his sides and between his legs, as well as to his feet, and sinapisms were applied to the back of the neck, and calves of the legs. His stimulants, at the same time, were increased in quantity. On making a careful examination of the surface of the body, we discovered now, for the first time, several purple, well-defined spots. They existed chiefly on the lower extremities and back. They were irregular in shape, and varied in diameter from one to three or four lines. A particularly large spot was discovered on the inside of the right knee simulating remarkably a bruise.

I gave directions to have his head shaved, and at the suggestion of my colleague, Mr. Croly, I ordered ten grains of the unguentum hydrargyri to be rubbed into each axilla, and three grains of quinine to be added to each stimulant enema; as the bowels had acted regularly up to the day before no purgative medicine or enema was given.

Eleven P.M.—Pulse 100, considerably stronger and more regular than at six o'clock, though still somewhat small; respiration continued blowing, and slightly stertorous at times. He would not swallow anything, but took into his mouth whatever was offered, and after a minute or two invariably spit it out. He was on the whole very obedient, but would make no attempt to answer questions. There was no evidence of urine in the bladder, though he did not pass water since he came in, about twelve hours previously. Extreme hyperæsthesia was evinced by the patient whenever he was rubbed, pinched, or percussed on any part of the body, but especially on the spine and legs. At each percussion he started violently, and the intensity of the shock seemed to be in direct proportion to the nearness of the part struck to the spine.

It was ordered, at Dr. Benson's suggestion, to have five grains of blue pill rubbed up with each injection, and to have the patient's head blistered with Tichborne's vesicating collodion.

Tuesday.—The patient was perfectly unconscious, and incapable of being roused; the pulse feeble, intermitting and remitting, and extremely difficult to count; its frequency was about 160; respiration was puffing and blowing, and very laboured; pupils rather contracted, and not obedient to stimulus of light. The surface of the body was warm, and a general purplish hue was now visible over the greater part of the body, especially on the legs and nates.

Hot jars were applied still to the feet and the inside of his thighs. The firing button was applied along the spine, from the occiput to the sixth dorsal vertebra, so as to produce three parallel rows of vesications, each blister being about an inch from the one above and below, and each row being about half-an-inch from its fellow, a proceeding suggested by my colleague Mr. Tufnell. After this, which seemed to cause but little, if any, pain, he appeared somewhat roused from the completely comatose condition in which he was previously, but yet he showed no evidence of intelligence. Respiration, however, became deeper and more free. No urine was found in the bladder. He had not passed anything from either bladder or bowels since he came into hospital. Coffee-ground matter now began to be vomited, or rather it welled up through the mouth and nose, and about two o'clock the same day the patient died.

No retraction of the head existed at any time during the patient's illness, nor stiffness of the muscles of the neck. There were no well-marked convulsions, though convulsive startings were frequent.

Post-mortem.—About twenty hours after death the post-mortem examination was made. Rigor mortis was well established. That peculiar plum-purple discolouration so often observed in these cases, was well-marked on the legs, especially their posterior aspects, on the back, nates, back and sides of the neck and ears. Those parts of the body which pressed on the table, such as portions of the backs of the shoulders, nates, calves of legs, and heels, were pale and almost free from discolouration. The purple spots differed from their appearance during life only in having become more red in colour. A slightly greenish tinge was observable on the abdomen, and a large bulla on the outer maleolus. On making an incision through the scalp from ear to ear, to examine the contents of the skull, a hissing sound was heard, as of gas escaping through small orifices, followed immediately by a very fœtid odour. When the calvarium was removed, and the dura mater exposed, the sinuses and veins of the latter were seen to be considerably distended. On removing the dura mater about one ounce of clear fluid escaped from the cavity of the arachnoid. The larger veins ramifying on the surface of the brain were seen to contain, besides some dark blood, a very remarkable quantity of gas, so much so that in some parts the blood was entirely displaced to a considerable extent, and the veins assumed the appearance of semi-transparent, multilocular, inflated tubes. In removing the brain from the skull, when the vertebral veins were divided, gas and blood issued slowly from the proximal extremities of each, causing, thereby, a welling up of bloody froth to the extent of about the measure of half a fluid drachm. There was, here and there, a trace of recent opacity of the arachnoid, at the base of the brain, and slight capillary congestion, but no appearance of lymph or pus. The substance of the brain was healthy. In each lateral ventricle, about ten minims of clear redish serum was found.

The spinal cord was next to be exposed, and in doing so a very remarkable phenomenon presented itself. When the muscles were cleared away from each side of the spinous processes of the vertebra, so as to allow the laminæ to be divided, the deep furrows so made became rapidly filled up with bloody froth, exactly similar to that which accumulated about the proximal ends of the divided vertebral veins. At two or three points in these grooves large bubbles of gas rose to the surface, and burst with a succession of audible snaps. When this froth was wiped away with a sponge, the grooves became quickly refilled with similar contents, and this was done several times with the same result. When the theca of the cord was exposed, its large veins were seen to be considerably congested. When this covering was slit up, and the cord exposed, a very slightly reddish blush was apparent over the greater part of its surface, but no lymph nor pus was found.

When the chest was opened, the lungs were found to be very much congested with dark venous blood. Under the pleura, in many places, considerable collections of gas were seen forming large bullæ. These were situated, particularly in the angles of the fissures where the pleura is reflected from one tube to the other, and resembled the subpleural form of emphysema. No other form of emphysema, however, was present. In the cavity of the pericardium about six ounces of turbid bloody serum was found. Wishing to separate the heart from the lungs without removing the latter from the body, I proceeded to divide the great vessels. In doing so a great quantity of bloody froth issued from both extremities of the divided pulmonary artery, and from the superior and inferior vena cava. No froth was found in the aorta, nor in the pulmonary veins. From the cavæ there flowed, besides this froth, a great quantity of dark blood mixed with excessively black tary clots. The right cavities of the heart were found distended, with very black, loosely clotted blood, mixed with some froth. The structure of the heart was remarkably healthy. In the cavity of the peritoneum about ten ounces of bloody serum were found. Between the layers of the omental peritoneum a considerable quantity of gas was found, but not in connection with any other part of that membrane. The liver, spleen, stomach, kidneys, and bowels were all congested, but presented no special appearance worth recording.

Case 2.—R. T., æt. 42, a commercial traveller, was admitted into the City of Dublin Hospital by the Purser-Student on June 14th, 1868. The man was suffering from severe diarrhœa, accompanied with intense vertigo, and was placed under the care of Mr. Croly, as there was no medical vacancy.

On Sunday, 15th, I saw him in consultation with my colleague, Mr. Croly. I then learned that he had been subject for the previous eight months to repeated and uncontrollable attacks of epistaxis, the last attack being about ten days before his admission. He had been a hard drinker for many years also. When I saw him on Sunday evening, about nine o'clock, I found that the diarrhœa had been checked since the previous day. He was then lying tranquilly on his back; his eyes had a wild expression, and he complained of slight headache. When addressed, he answered perfectly rationally, and with great intelligence, but presently, by his incoherent expressions, he showed that his mind was wandering. His pulse was 98, very small, and but slightly irregular. Respiration was somewhat laboured and frequent. His temperature, too, was slightly above the healthy standard.

Several purple spots were seen on the buttocks, thighs, legs, and feet. These spots varied from the size of the head of a pin to three or four lines in diameter. They were very irregular in shape, and were of a much brighter purple than is usually seen in cases of fibris purpurea. No spinal tenderness existed in any part, nor was there any retraction of the head or stiffness of the muscles of the neck. At the base of the left lung there was some dulness, and immediately above this was heard a fine pneumonic crepitus, extending over the lower half of the left side of the chest. At both base and apex of the heart was heard a loud systolic bruit, and a slight diastolic murmur at the former position. There was also evidence of a considerably enlarged liver.

The patient was ordered bark and chlorate of potass, with diffusible stimulants, and a large linseed-meal poultice was applied to the back of the left side of the chest.

After this he passed the night well, and slept tranquilly, but in the morning I was told he became highly delirious and restless, and died before I saw him.

Post-mortem.—About three and a half hours after death, the post-mortem examination was made. Rigor mortis was then well established. There was extreme plum-purple discolouration on the back, except on the sacrum and buttocks, and on the backs of the shoulders, where the body pressed on the board. There was a slight, similar, discolouration on both front and back of the thighs, and on the backs of the legs. On the back and sides of the neck the same was of a deep tint. Bright purple circumscribed spots were scattered over face, head, legs, feet, and back; a few minute ones on the abdomen and chest, and several very small ones on the backs of both hands. These latter were distinctly elevated, and some of the former were slightly so. On the conjunctiva covering the right external canthus several minute purple spots were visible. The superficial veins on the neck, upper portion of the chest and arms, were very prominent and blue, and a bright red vascularity of the intervening skin was very apparent. On making an incision with a scalpel through the cuticle covering one of the larger spots on the back two or three large drops of dark fluid blood rapidly ran down the shoulders. This happened with all the elevated spots whose cuticle was incised, but not with the non-elevated.

The internal appearances in this case were of a very negative character, but yet important.

The veins on the surface of the brain, and the sinuses, were but slightly congested. About one ounce of clear fluid was found in the cavity of the arachnoid, and a considerable quantity of similar fluid infiltrated the meshes of the *pia mater* on the vertex. Not the least trace of inflammation was found in any part of the membranes of the brain. The substance of the brain was firm and remarkably healthy. A trace of reddish serum was found in the lateral ventricles. On opening the spinal canal, the theca of the cord was seen presenting a pale, perfectly healthy appearance, and when this covering was slit up, the cord itself was found to be equally healthy. Not the least trace of inflammation or vascularity was visible anywhere. Even the larger veins, which, in almost every case are congested, were, in this case, perfectly natural, and the whole cord might be shown as an excellent specimen of a healthy one, pale in colour, and firm in consistence.

When the chest was opened about half a pint of clear fluid was found in the cavity of each pleura, slight hepatization at base of each lung, and splenization of the lower half of the left lung. About an ounce of clear fluid was found in the pericardium, but no appearance of inflammation. The right cavities of the heart were distended with dark fluid blood mixed with coagula. The left ventricle was hypertrophied; and on opening this cavity, very extensive aortic valve disease was discovered, vegetations of enormous size adhering to the flaps of the valves. Some thickening of the curtains of the mitral valve existed also. The liver was considerably enlarged, and presented a good example of the nutmeg form of the disease. Spleen, kidneys, and bowels were all congested; a few small spots were found on the surface of the parietal peritoneum.

Observations.—From Case 2 one obvious inference at least can be drawn, viz.—that whereas the patient presented quite the appearance, and many of the symptoms, of the epidemic disease under consideration, he did not die from the effects, whether primary or secondary, of any inflammation.

With reference to Case 1, the first question that naturally arises is, what was the cause of that excessive quantity of gas found in the veins, and appearing in the grooves made at each side of the spinal column during the autopsy? That the gas in the vessels had its origin in some change in the blood cannot be questioned. But what was the nature of that change? was it decomposition, or a process analogous to fermentation? As to the first hypothesis—the patient had been dead only twenty hours, and had been lying during that time in a cool, dry mortuary, the weather being mild, but not hot. The only other sign of decomposition was the slight greenness on the abdomen, and we have all repeatedly made post-mortem examinations when the patients had been dead for a much longer time, and where decomposition of the tissues had proceeded much farther, and yet where no such emphysematous condition of the blood was found. It is clear, therefore, that something else beside the ordinary causes of putrefactive changes must have been present here.

Various authors have described cases in which this condition was found either actually preceding death, or very quickly following it, but in all these cases, as far as I am aware, some septic or zymotic agency was at work. For example, Huxham observed the development of emphysema in a patient affected with putrid fever, sore throat, and non-coagulable state of the blood, and believes that this frequently happens in putrid malignant fevers. Copland noted the same in some cases of scarlatina and analogous diseases; while Frank, Bally, and Morgagni met with it in fever. Of course I do not ascribe a septic or zymotic origin to the insignificant amount of gas occasionally found in the veins of the meninges, as in the cases cited by Hallé, Morgagni, Nysten, Lélut, and others, and more than one example of which I have met with myself, and seen, through the kindness of my colleague, Dr. Hewitt. In these cases it is highly probable that the external air may have entered the divided extremities of the vessels, as suggested by Dr. W. H. Walshe. If, therefore, we consider the gas to be a product of decomposition, we must suppose the blood to have been so altered in its nature before death, as to favour early and rapid putrefaction. Mere inflammation, of such nature and extent as existed in this case, could not do that, it must have been some tonic agent.

As to the second hypothesis—that of the gas being a product of a process analogous to fermentation, no one, I think, will deny that the process was set up by the zymotic agency of some poison in the blood.

These two cases then, though differing widely from each other, both tend to exactly the same conclusion, and, when taken conjointly, go very far to prove, even if we had no other evidence, that the disease is not primarily or essentially an inflammation of the cerebro-spinal membranes, as some maintain, and as the names adopted by many would indicate, but originates in some grave lesion of the blood—some epidemic blood-poisoning, the meningeal lesions being secondary and by no means a necessary part of the disease, any more than sore throat is a necessary part of scarlatina.

Assuming, then, that the disease has a zymotic origin, the inflammation of the cerebro-spinal membranes cannot be considered as anything else than a symptom which, though frequent, is by no means invariable. Are we right, therefore, in naming the disease after a symptom—in calling it cerebro-spinal arachnitis, or cerebro-spinal meningitis, or epidemic meningitis? The second of these names is used by Burdon Sanderson, while the last is preferred by Stillé, though that author speaks of "its double character as a blood disease and an inflammation of the cerebro-spinal membranes."

In this sentence he virtually adopts the assumption I have made above, viz.:—"that the disease has a zymotic origin," and yet he calls the disease epidemic meningitis, thus naming it after what really seems to be but a symptom. It is true, however, that he says elsewhere, "So constant a lesion cannot be accidental, and must be essential. The inflammatory element and the septic element are both necessary to constitute the disease." He cannot, therefore, be indicted with the charge of naming it after a symptom, though even adopting his view, the name epidemic meningitis gives undue prominence to the so-called "inflammatory element," to the exclusion of the "septic element."

In using the name *purpuric fever*, I do so, not as being a good one, but merely for want of a better. However, I think I have proved satisfactorily that it would be a less objectionable name than any of those which assume the inflammatory element to be an essential constituent of the disease.

ON THE ANATOMY AND PHYSIOLOGY OF THE CORONARY ARTERIES OF THE HEART.

BY ALEXANDER MACALISTER, L.R.C.S., L.K.Q.C.P.,
DEMONSTRATOR OF ANATOMY, ROYAL COLLEGE OF SURGEONS, IRELAND; SURGEON TO THE ADELAIDE HOSPITAL; HON. PROFESSOR OF ANATOMY TO THE ROYAL DUBLIN SOCIETY.

THE vascular supply of the heart substance presents many features of interest which have not been entirely overlooked by modern physiologists, but whilst recently engaged in examining the coronary vessels and their actions, I have been struck with several points in connection with cardiac physiology, which have not, perhaps, received the attention which they deserve. The descriptive details of the position, course, and relations of the two coronary arteries are so fully given in almost every anatomical treatise, that I will forbear alluding to more than two points in this respect. In the first place, it is, perhaps, not sufficiently recognised that the vascular supply of the two sides of the heart is to a considerable extent independent. Professor Hyrtl,[1] of Vienna, was the first to demonstrate that one coronary artery cannot be injected from the other, as no trunks larger than capillaries unite their terminal branches in the ventricular substance. At the same time the experiments of Schiff show indirectly that the vascular supply of each side of the heart is derived solely from a single coronary vessel, and that the existence of aberrant branches from the right artery to the left ventricle, and *vice versa*, is exceptional. The second important point in anatomical detail refers to the point of origin of these vessels. Among the older anatomists, as Boerhaave, Carpus (1530) Riolan,[2] Verheyen,[3] Forsten[4] we find that the coronary arteries are described as arising behind the semilunar valves, that these curtains, when raised, would be so placed as to block up their mouths, and in more recent times, Vaust,[1] Brücke, and a few others, have advocated the same opinion; the elder authors based their belief on the appearance of the parts as seen on dissection after death, but Vaust has arrived at the same conclusion from experimental researches, as he found that by injecting the heart through the pulmonary vessels, the coronary arteries were not filled; in the hands of Hyrtl, however, the same experiment was attended with a contrary result, for from the pulmonary veins he was able to fill the coronary arteries.

Sömmering, Blancard, Rolfincius, and Morgagni, among old anatomists, and Cloquet, Harrison, and Power, among moderns, describe them as being placed above the level of the valves, so far as to be beyond the range of contact with them. Quain describes the mouths of these vessels as on a level with the top of the valves, within range of contact, but not of occlusion. The condition which I have found most commonly is the last, but I have seen the second arrangement, and in many cases I have noticed the left as being within contact-range of the valve, while the right was above its level. I recollect once, when a student, seeing an aorta in which the valves were perfectly capable of occluding the arteries, but this last condition I regard as one of great rarity. Morgagni, indeed, mentions that he is doubtful on the true typical position of the vessels, in some subjects the vessels being above, and in others below the valve-level; and Petriolus, premising that in carnivores the coronaries arise above the valves, and in herbivores behind them, draws the conclusion that the courage of the former and the timidity of the latter arise from the fact of the greater or lesser degree of nutrition of the heart. Hence he argues that the difference between timid and brave men depends on the relation of the orifices of the coronary vessels to the semiunlar valves, a brave man having his coronary arteries above the valves, and a timid man behind them! These arteries are rarely the subjects of variety. Camper records having once seen a single coronary artery. Similar cases are recorded by Bochdalek, Junior, of Prague,[2] Thebesius,[3] and Columbus.[4] Meckel describes an example in which four trunks arose from the aorta, and Winslow has recorded the existence of three of these vessels. Among animals, the number and arrangement of the coronary vessels is subject to little variety. The elephant, according to Camper, possesses only one artery; the cow, pig, goat, hare, rabbit, dog, and cat—like man—have two of these vessels; and this seems the usual number in vertebrates. In one instance Morgagni found three in a dog.

Prof. Hyrtl, of Vienna, has described the hearts of urodelous batrachians, and some families of reptiles, as destitute of true nutrient arteries, with the exception of a superficial stratum of capillaries on the outer side, as in these the coronary artery is principally distributed to the bulbus aortæ, and mentions that these hearts are mainly nourished by direct imbibition from the ventricular cavities. The same disposition occurs in the hearts of many osseous fishes, and in connection with these Professor Hyrtl remarks that the hearts of these animals are remarkable as being nourished by venous blood. It was believed by some former anatomists that the human heart received a supply of blood from the ventricular cavities, communicating with the coronary arteries, but injection demonstrates the fallacy of this opinion.

Closely depending on the point of origin of these vessels is the period during which the blood enters them. Many of the older anatomists, who believed that the vessels were occluded by the valves, thought that blood could not enter into these arteries until the ventricular systole was concluded, and the semi-lunar valves were closed. According to this idea, the coronary arteries would be the last supplied with blood. Morgagni was among the first to show that if the coronary arteries were placed above the level of the valves, there could be no mechanical obstacle to the entrance of the blood into the vessels at the period of ventricular systole, and hence most of the modern physiologists teach that the heart is nourished at the time of contraction, and thus, is supplied sooner than any other organ. This theory is supported by the observations of Haller, who saw the blood coming *per saltum* from the cut extremity of a coronary artery during ventricular systole, and Endemann observed the mercury in a monameter to be elevated during the same period when the instrument was introduced into one of the arteries in an artificially stimulated heart. Mierswa,[1] in supporting the same idea shows by experiment that the semi-lunar valves are never applied against the wall of the sinus of Valsalva during systole, and consequently, they can never close the coronary arteries. Similar experiments and observations have been made by Rudinger[2] and Joseph[3] confirming the same statement. But, while accepting this theory, that these vessels are first supplied, we must likewise consider that an important mechanical obstacle exists to prevent the blood from traversing the heart wall during ventricular systole. During that action the contracted muscular fibres compress the blood-vessels, and so preclude the perfect nutrition of the tissue of the organ, for we know that during the prolonged contraction of any ordinary muscle the superficial veins always become distended and the arterial currents are interrupted. If, then, the heart depended for its vascular supply upon the quantity of blood entering it during systole, it would be imperfectly nourished, but as the ventricle relaxes, a reflux takes place with force sufficient to shut down the semilunar valves, and the mouths of the coronary vessels being open, receive the blood; thus a second stream enters these arteries, impelled by the force of gravity and the elasticity of the aorta, while the muscular fibres relaxing relieve the smaller blood-vessels of their constriction, causing a certain amount of *vis a fronte* or suction force. We thus have reason to believe that the vessels in the heart-wall receive two blood-currents for each single stream in any other artery, one an effluent, and the other a refluent supply. This idea was first put forward by Professor Hyrtl, and is one supported by many facts both of anatomy and physiology, and in connection with it, we have to consider what part in the mechanism of nutrition each current plays. The systolic or effluent current I regard as the least efficient, but as it is sent with great force, it will probably carry a quantity of blood into the auricular wall, into the coats of the origin of the aorta and of the pulmonary artery. The diastolic or refluent current, although more copious, is less forcible, but traverses probably the ventricular vessels, and nourishes the tissue of this part of the organ.

[4] This anatomist and Blancard describe one coronary artery as the typical arrangement.

The object subserved by this double current is the perfect nourishment of the heart, as it requires a larger supply of blood than any other muscle in the body. This we might expect on *à priori* grounds, for we have reason to believe the amount of chemical action taking place in a muscle to be in the direct ratio of the amount of exertion. It is also palpable that the amount of blood required for the nourishment of a muscle, is in direct proportion to the amount of material disorganized, *i.e.*, to the amount of chemical action in progress, and as the heart performs more work than any other muscle of its size, we believe that it requires a proportionately large supply of blood. Professor Haughton has calculated the exertion undergone by the heart in the course of twenty-four hours to be equal to the raising of 124·6 tons to the height of one foot, and as the labouring force of man averages, according to Haughton[4] and Donders, equal to the lifting of 340 tons to the height of one foot a-day, it will be seen that the heart does in one day more than one-third as much as all the other muscles in the body—hence any interference with the nutrition of the organ produces an immediate effect upon cardiac action, as proved by the experiments of Erichsen and Schiff. Von Bezold[1] more recently found that when the coronary arteries of rabbits were temporarily occluded, the pneumogastric and cervical sympathetics having been already divided, the heart's action became rapid and irregular after fifteen seconds, and finally, after from one minute to one minute and a-half, the ventricles ceased to act, the auricles continuing a weak, intermitting action for a greater length of time.

The capillaries of the heart are remarkable for their number, and the veins are nearer the surface and more muscular than the generality of such vessels elsewhere.

SHORT NOTES ON NICE.

By JAMES STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS, IRELAND; SURGEON TO JERVIS-STREET HOSPITAL; CONSULTING SURGEON TO THE COOMBE LYING-IN HOSPITAL; SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD, ETC.

No. IV.

"Professor Sigmund, of Vienna, specifies, among the disadvantages of Nice, the presence of dust at all seasons and the want of cleanliness of the streets. In these respects, however, an improvement has taken place since the annexation—the streets are cleaner and better watered, and the dust is only inconvenient when there is much wind. This writer enumerates among the advantages of the place, a prevailing mild temperature in winter, the infrequency of high and cold winds at this season, as also of rain; the absence of hail or snow, a sunny dry air, the rich and varied vegetation, and the favourable opportunity for taking out-door exercise. 'The air,' he observes, 'is drier here than at any other place of resort in Italy, which is very sensible in sharp and changeable March. Sudden changes of warm and cold dry days, with the moist evenings and night air, especially in the suburbs.'"[2]

Smollett in writing on the climate of Nice says—"The constitution of this climate may be pretty well ascertained, from the enclosed register of the weather, which I kept with all possible care and attention. From a perusal of it you will see there is less wind and rain at Nice than in any other part of the world that I know; and such is the serenity of the air, that you see nothing above your head for several months together, but a charming blue expanse without cloud or speck. Whatever clouds may be formed by evaporation from the sea, they seldom or never hover over this small territory; but in all probability are attracted by the mountains that surround it, and there fall in rain or snow. As for those that gather from other quarters, I suppose their progress hitherward is obstructed by those very Alps which rise one over another, to an extent of many leagues. This air being dry, pure, heavy, and elastic, must be agreeable to the constitution of those who labour under disorders arising from weak nerves, obstructed perspiration, relaxed fibres, a viscidity of lymph, and a languid circulation. In other respects, it encourages the scurvy, the atmosphere being undoubtedly impregnated with sea-salt. . . .

"I must also acknowledge, that ever since my arrival at Nice, I have breathed more freely than I had done for some years, and my spirits have been more alert. The father of my *œconome*, who was a dancing-master, had been so afflicted with an asthmatic disorder that he could not live in France, Spain, or Italy, but found the air of Nice so agreeable to his lungs, that he was enabled to exercise his profession for above twenty years, and died last spring, turned seventy. Another advantage I have reaped from this climate, is my being, in a great measure, delivered from a slow fever which used to hang about me, and render life a burden. Neither am I so apt to catch cold as I used to be in England and France; and the colds I do catch are not of the same continuance and consequence as those to which I was formerly subject. The air of Nice is so dry that in summer, and even in winter (except in wet weather) you may pass the evening, and indeed the whole night, *sub dio*, without feeling the least dew or moisture; and as for fogs, they are never seen in this district. In summer the air is cooled by a regular sea-breeze blowing from the east, like that of the West Indies. It begins in the forenoon, and increases with the heat of the day. It dies away about six or seven; and, immediately after sunset, is succeeded by an agreeable land-breeze from the mountains. The sea-breeze from the eastward, however, is not so constant here as in the West Indies, between the tropics, because the sun which produces it is not so powerful. This country lies nearer the region of variable winds, and is surrounded by mountains, capes, and straits, which often influence the constitution and current of the air. About the winter solstice, the people of Nice expect wind and rain, which generally lasts, with intervals, till the beginning of February. But even during this, their worst weather, the sun breaks out occasionally, and you may take the air either a-foot or on horse-back every day, for the moisture is immediately absorbed by the earth, which is naturally dry. They likewise lay their account with being visited by showers of rain and gusts of wind in April. A week's rain in the middle of August makes them happy. It not only refreshes the parched ground, and plumps up the grapes and other fruit, but it cools the air and assuages the heats, which then begin to grow very troublesome; but the rainy season is about the autumnal equinox, or rather something later. It continues about twelve days or a fortnight, and is extremely welcome to the natives of this country. This rainy season is often delayed till the latter end of November, and sometimes till the month of December, in which case, the rest of the winter is generally dry. The heavy rains in this country generally come with a south-west wind, which was the *creberque procellis Africus* of the ancients. It is here called *Lebeche*, a corruption of *Lybicus*; it generally blows high for a day or two, and rolls the Mediterranean before it in huge waves that often enter the town of Nice. It likewise drives before it all the clouds which had been formed above the surface of the Mediterranean. These being expended in rain, fair weather naturally ensues. For this reason, the Nissards observe *le Lebeche raccommode le tems*. . . . . . .

"I have described the agreeable side of this climate, and now I will point out its inconveniences. In the winter, but especially in the spring, the sun is so hot that one can hardly take exercise of any sort abroad, without being thrown into a breathing sweat; and the wind at this season is so cold and piercing, that it often produces a mischievous effect on the pores thus opened. If the heat rarifies the blood and juices, while the cold air constringes the fibres, and obstructs the perspiration, inflammatory disorders must ensue. Accordingly, the people are then subject to colds, pleurisies, peripneumonies, and ardent fevers. An old count advised me to stay within doors in March, *car alors les humeurs commencent a fe remuer*. During the heats of summer, some few persons of gross habits have, in consequence of violent exercise and excess, been seized with putrid fevers, attended with exanthemata, erysipelas, and milliary eruptions, which commonly prove fatal; but the people in general are healthy, even those that take very little exercise: A strong presumption in favour of the climate!"

Sir James Clark, in his valuable work on "The Sanative Influence of Climate," makes the following interesting remarks on Nice, viz.:—

"The climate of Nice approximates more nearly in its general character to that of Provence, which has just been described, than to any other. Its mean annual temperature is 59°, being 9° warmer than London, 7° warmer than Penzance, 1° colder than Rome, and 5° colder than Madeira. The mean temperature of *winter* is 48°; that is, nearly 9° warmer than London, 4° warmer than Penzance, 1° colder than Rome, and 12° colder than Madeira. The mean temperature of *spring* is 56°; being 7° warmer than London, 6° warmer than Penzance, 1° colder than Rome, and 6° colder than Madeira. The temperature throughout the year is more equally distributed at Nice than at any other place in the South of Europe, except Rome and Cadiz; the difference of the warmest and coldest months being only 28°, and the mean difference of successive months only 4°·74.

"The range of temperature for the day is also less at Nice than at any other part of the South of Europe; and in steadiness of temperature it ranks next to Madeira.

"The mild and equable character of the climate of Nice depends in a great measure on the position of the place with respect to the neighbouring mountains and the sea. The maritime Alps form a lofty barrier, which shelters it in some degree from northerly winds during winter; and the cool sea breeze, which prevails every day with a regularity almost equal to that of a tropical climate, moderates the summer heat. 'Cet alizé Méditerranéen,' says M. Risso, 'toujours doux, frais et tranquille, s'elève périodiquement vers neuf à dix heures du matin, cesse souvent vers les quatre heures après midi, et s'étend dans l'intérieur de nos Alpes rarement au dela de huit myriamétres.'[1] These circumstances explain the small annual range of temperature at this place, already noticed, and which a reference to the table in the appendix will show to be much less than in most parts of Italy.

"Notwithstanding the extent, however, to which Nice and its environs are encircled by mountains (and it is so in a great measure from W.S.W. to E.S.E.), it is by no means exempt from cold winds during the winter, and still less so during the spring. The easterly winds are the most prevalent during the latter season. They range from east to north-east, frequently blow with considerable force, and are often accompanied with a hazy state of atmosphere. Sometimes this wind commences in the forenoon, at other times not until the afternoon. When the early part of the day is fine, it never should be lost for exercise, as a cold windy afternoon not unfrequently succeeds a calm mild morning.

"From the north-west or *mistral*, which is the scourge of Provence, Nice is pretty well sheltered. The force of this wind seems to be broken, and directed to the southward by the Estrelles, a chain of mountains between Frejus and Cannes. But although the mistral is not experienced in its full force at Nice, or only towards its termination, when it takes a more westerly direction (*la queue de la mistral*), the keen, dry quality of the air is very sensibly felt whilst it prevails. It sets in generally about two or three o'clock in the afternoon, and is not of long duration. The wind seldom blows strong directly from the north, though the air is very sharp when it is in that quarter. The northerly gales, descending from the summits of the high range of mountains which encircle the valley of Nice on the north, are little felt; they appear to pass in an oblique direction over the town.[2] The sirocco is of rare occurrence, and when it does pay a visit in the winter, it is gentle, and not unpleasant to the feelings of invalids in general.

"The weather at Nice during the winter is comparatively settled and fine, the atmosphere being generally clear and the sky remarkable for its brilliancy. The temperature seldom sinks to the freezing point, and when it does, it is only during the night; so that vegetation is never altogether suspended. Indeed, at Nice, winter is a season of flowers, the dryness of the air rendering the same degree of cold less injurious to them than it would be in a more humid atmosphere. Spring is the most unfavourable season; the sharp, chilling, easterly winds are the greatest enemy with which the invalid has to contend; and the prevalence of these during the months of March and April forms the greatest objection to this climate, especially in pulmonary diseases.

---

[1] "'Histoire Naturelle de Principales Productions de l'Europe Méridionale, et particulierement de celles des Environs de Nice.' 1826. par A. Risso. Vol. i. p. 219. To this excellent work I beg leave to refer those of my readers who may be desirous of information respecting the natural history of the South of Europe."

[2] "'On éprouve fort rarement,' says M. Risso, 'toute sa force dans les couches inférieures de l'air qui environnent le plateau de Nice, à cause du triple rang de montagnes qui l'entourent; il occupe presque toujours les couches supérieurs, et descend en pente comme un grand torrent aérien sur la mer; car on aperçoit à un kilomètre du rivage qu'il commence à en friser la surface pour former un peu plus loin des vagues qui, s'elévant les unes sur les autres, vont porter les tempêtes sur les côtes boreales d'Afrique.'—*Hist. Nat.* vol. i. p. 216."

"It must not be supposed, however, that these sharp spring winds are peculiar to Nice. They prevail more or less over the whole south of Europe. They are equally bad at Naples; somewhat softened at Pisa; and still more so, perhaps, at Rome.

"The climate of Nice is altogether a very dry one. Rain falls chiefly during particular seasons. From the middle of October to the middle of November it generally rains a good deal; also about the winter solstice there is commonly some rain, and again after the vernal equinox. The quantity of rain that falls during the year has not been accurately estimated.

"Upon the whole, in the physical qualities of its climate, Nice possesses considerable advantages over the south-east of France, more especially in being protected from the mistral.

"Nice is upon the whole a healthy place. Catarrhal affections and inflammation of the lungs rank among the most frequent diseases of the inhabitants. They are especially common and violent in the spring, and are generally complicated with irritation of the digestive organs. Pulmonary consumption is much less frequent than in England and France. Gastric fever and chronic gastritis are very common diseases. Indeed, gastric irritation appears to be very prevalent, and almost all other diseases are complicated with it. Intermittent fevers are not unfrequent among the peasantry living or labouring in unhealthy situations in the country. The flat ground on the banks of the Var is the most fruitful source of these fevers. The guards stationed on the bridge which crosses this boundary stream, are frequently attacked with ague during the unhealthy season, although they are stationed there only a few days at a time. This is a disease, however, from which the winter resident at Nice has nothing to fear. Dr. Skirving, during a long residence there, met with one case only of ague amongst the strangers. Diseases of the eyes are very prevalent, particularly amaurosis and cataract; cutaneous diseases are also very common.

"In describing the effects of the climate of Nice on disease, I am much indebted to Dr. Skirving for the results of his extensive experience.[1]

"In consumption, the disease with which the climate of Nice has been chiefly associated in the minds of medical men in this country, little benefit is to be expected from the climate. When this disease is complicated with an irritable state of the mucous membranes of the larynx, trachea, or bronchi, or of the stomach, the climate is decidedly unfavourable; and, without extreme care on the part of the patient, and a very strict regimen, the complaint will in all probability be aggravated by a residence at Nice. Indeed, the cases of consumption which ought to be sent to this place are of rare occurrence. If there are any such, it is when the disease exists in torpid constitutions, and is free from the complications which have been just mentioned. Even the propriety of selecting Nice as a residence for persons merely threatened with consumption, will depend much upon the constitution of the individual. Dr. Skirving met with cases which left no doubt on his mind that a residence for one or two winters often proves of advantage, as a preventive measure, in young persons predisposed to this disease; and even in some instances in which there was every reason to believe that tubercles already existed in the lungs, the climate has appeared to be useful. But in the advanced stage of consumption, his opinion, founded on eight years' experience, accords with what has been already stated; and this is still further supported by the testimony of Professor Foderé, of Strasbourg, who resided six years at Nice.[1] Indeed, sending patients labouring under confirmed consumption to Nice will, in a great majority of cases, prove more injurious than beneficial.

"In chronic bronchitis, which often simulates phthisis, very salutary effects are produced by a residence at this place. Such patients generally pass the winter with comparatively little suffering from their complaint, and with benefit to their general health. They are here able to be much in the open air, whereas if they had remained in England they would in all probability have been confined during the greater part of the winter to the house. The particular kind of bronchial disease most benefited by a residence at Nice is that which is accompanied with copious expectoration, whether complicated with asthma or otherwise; and in the chronic catarrh of aged people it is particularly beneficial. This variety of bronchial disease is directly the reverse of that which is mitigated by the south-west of France and of England: and I think it important here to remark, that unless the distinctions which I have pointed out in bronchial diseases, and their complications, are attended to, great errors must be committed in selecting a residence for such patients.

"The invalid subject to chronic gout may, in most cases, escape his usual winter attack, and provided he lives with prudence his general health may be improved, by a winter's residence at Nice.

"In chronic rheumatism the climate is generally very beneficial; and its advantages are also remarkable in scrofulous complaints. On children the climate generally exerts a very favourable influence, if attention be paid to their diet.

"In the numerous train of hypochondriacal and nervous symptoms which often originate in dyspeptic complaints, Nice is beneficial; but here again it is necessary to distinguish the particular character of the affection. The cases of dyspepsia most benefited are those accompanied with a torpid, relaxed state of the system, with little epigastric sensibility, and none of those symptoms which denote an inflamed or very irritable state of the mucous membrane of the stomach. Where the latter state prevails, Nice will decidedly disagree.

"In all cases where there is great relaxation and torpor of the constitution, the climate of Nice is extremely useful. In young females labouring under such a state of system, connected with irregularities of the uterine functions, either when these have not been established at the usual period, or when they have afterwards been suppressed, marked benefit may generally be expected. In indicating the class of cases alluded to as likely to derive advantage from the climate of Nice, I would designate them to the practical physician as those that are usually relieved by chalybeates.

"In a numerous class of patients, whose constitutions have been injured by a long residence in tropical countries, by mercury, &c., and on which a dry and rather exciting climate is indicated, Nice will prove favourable. Some cases of chronic paralysis not connected with cerebral disease have also been found to derive considerable benefit from a residence at this place.

"In stating its general influence on the animal economy, I would say that the climate of Nice is warm, exhilarating, and exciting, but to highly sensitive constitutions somewhat irritating, more especially during the spring. It is extremely favourable to the productions of the vegetable kingdom, some of which flourish here in a degree of luxuriance that is scarcely to be equalled in other parts of the south of Europe.[2]

---

[1] "Dr. Skirving practised at Nice with great reputation for many years; but for the last ten years he was mostly confined to his house by a paralytic affection, which carried him off last autumn."

[1] "See 'Voyage aux Alpes Maritimes, ou Histoire Naturelle, Agraire, Civile et Médicale du Pays de Nice,' &c. Strasbourg, 1823."

[2] "Peu de contrées méridionales de l'Europe offrent un tableau aussi varié en végétaux indigènes et exotiques que les environs de Nice. Dans le fond, c'est une masse d'oliviers qui s'étend sur toutes les collines, et dispairaît insensiblement à mesure qu'elle s'eloigne du rivage de la mer. Sur le devant, ce sont des orangers, des bigaradiers, des limoniers, disposés en jardins qui offrent toute la luxe des Hespérides Pour rélever la sombre verdure des uns et la monotonie des autres, des

"Invalids who pass the winter at Nice scarcely ever reside in the town. Some good houses, tolerably well situated and over-looking the terrace, are, however, now to be had; but in the suburb called the *Croix de Marbre*, and along the sea beach, from the town to the ridge of mountains where the plain terminates on the west, the largest and best houses are to be found; and here strangers generally reside. At the foot of the hill on which stood *Cimiez*, there are also good houses; and this is a situation preferable to the lower part of the plain for patients very susceptible of injury from damp; it is also more protected from the cold northerly winds, and altogether, perhaps, the best situation at Nice for invalids.

"Invalids should endeavour to arrive at Nice about the middle of October, or sooner, and should not leave it before the beginning of May. The inconveniences experienced from the spring winds here are felt in a much greater degree in the South of France; and, accordingly, invalids often suffer severely from the winds of Provence when they leave Nice too early. The invalid may move in the direction of Nice and Genoa at a much earlier period than it would be advisable for him to return over the Estrelles to Provence; and when the climate of Nice is found to disagree, a change in the spring in the direction of Genoa may in some cases be advisable."

TIME FOR GOING TO NICE, AND THE EXPENSES OF REACHING IT FROM DUBLIN: THE WAY TO GET THERE.

The invalid should, if possible, reach Nice, as pointed out at p. 18 by Dr. Travis, at the end of October at the furthest, when, as a general rule, he shall avoid severe weather on the road, and when, on his arrival at Nice, he shall have an opportunity of selecting suitable *southern* rooms in one or other of the three departments of the town.

In travelling from Dublin to London, the invalid can, if necessary, stop at Chester on his way.

The mode of reaching Nice from London, must to a great extent depend on the patient's state of health, his position in life, and his means of living; thus, if he is very feeble, and that he can afford to do so, he ought to be accompanied by some person (say a male relative or courier) conversant with travelling, with the route and with the language of the country; a person who, in fact, can arrange the time and mode of conveyance from place to place, take tickets, register and receive luggage, select rooms at hotels, and pay bills; indeed, unless a confirmed invalid can have all the foregoing done for him, he had far better, in my opinion, stay at home, for the taking of tickets and registering of luggage almost invariably occupy from twenty to thirty minutes, generally speaking in the early morning, and always in exposed halls or passages, full of draughts of cold air. The receiving of luggage requires from thirty to sixty minutes, generally in the advanced evening or late at night, and always in cold halls, open stations, or passages, where I have no doubt that the lives of many patients have been shortened by the combined influences of fatigue and exposure to cold.

In the journey from London to Paris, the invalid can, if the weather proves rough, on his arrival at Dover, and that he is a bad sailor, stop at the Lord Warden Hotel at that place, and wait there for a good sea passage, when he can cross over by the morning boat, if he has a good attendant, and that arrangements have been made for his reception at Paris, he ought to "*go through*" to that city, and drive to his hotel at once, leaving the charge of his luggage to his attendant. The other evening, a friend of mine was detained at the Paris terminus, on his arrival from Calais, from twenty minutes past six o'clock in the evening until close on nine o'clock, passing the family luggage and getting it conveyed to his hotel.

From Paris to Nice, a distance of six hundred and seventy-seven miles and a-half, the journey should, as a general rule, be broken by an invalid three or four times on the road. Many people select Dijon, Avignon, Lyons, and Marseilles as resting places, on their way from Paris to Nice.

At Dijon I would recommend the traveller to go to the hotel Jura, which is next to the railway station, and is both a good and reasonable house.

At Lyons, the Hotel de l'Europe is very well spoken of, but I would recommend an invalid to put up at one of the many other hotels nearer to the station. I should say the Hotel du Louvre, or the Deux Mondes are the best.

As a general rule, but especially late in the season, an invalid should not stop at Avignon, it being about the coldest place a patient could select. A friend of mine, last year, on his way to Nice for his health, who was not able to leave Dublin until late in the season, wrote to me from Avignon as follows:—"An invalid who survives a night at Avignon in November is not going to die; it is the coldest place I ever was in; the wind does not blow there, it groans, it roars, as if it came down from a bellows, driven by an engine over a hundred miles of snow. It comes down the chimneys in a most frightful way. The houses are built to be cold: flat roofs, large windows that open to the floors, open fire-places as large as those in a forge, tiled floors in the bed-rooms and passages, no curtains, doors that wont shut; in fact I never spent such a night as I did at Avignon, and that I escaped with my life is a wonder." There is no doubt that Avignon is, as I have experienced myself, a very cold place, and therefore ought, if possible, to be avoided by a delicate person in search of health.

The Grand Hotel at Marseilles is a very comfortable and well-managed establishment, and is not very expensive, considering the excellent manner in which it is conducted.

The journey from Marseilles to Nice by railway, which is accomplished in a little under six hours, is a very agreeable one, the scenery along the entire line being both varied and beautiful.

Some physicians recommend patients who are not wealthy, and who, therefore, cannot well afford the expense of bringing attendants with them, to travel uninterruptedly from Paris to Nice by express train, a journey which is accomplished in about thirty hours; but I know by experience that even to a person in health the through journey from Paris to Nice is a very fatiguing one, indeed, I therefore cannot recommend it to an invalid, unless under extraordinary circumstances, and then he should engage a *coupé lit* carriage, in which he can recline as often as he is disposed to do so whilst on the road.

With regard to the hotels of Nice they are very numerous, and generally speaking well conducted, but the invalid should, in the choice of a residence at Nice, be guided, to a great extent, by the advice of one of the resident physicians, who, after getting an insight into the patient's state of health, will point out the proper department in which he should settle down.

The cost of travelling from Dublin to Nice by mail steamers, and first-class express trains, including hotel expenses at the various resting-places, porterage, cab-hire, &c., on the way, amounts, in round numbers, to £16.

The expense of living at Nice will much depend on the class of hotel or boarding-house, and the department selected. The cost of living at a first-class hotel in the modern parts of Nice, or at Carabacel, without a private sitting-room, amounts to from 16 to 20 francs a-day, whilst boarding-houses charge from 7 to 12 francs a-day, but there are some of the latter, I am told, in the more inland parts of Nice, where patients are boarded and lodged for about 5 or 6 francs a-day.

A suite of rooms, including two or three bed-rooms and a large sitting-room, at one of the best hotels in Nice, cost, as a general rule, from 35 to 40 francs a-day; this, however, includes servants.

IT is stated that during the four or five days preceding the 16th ult., more than 250 deaths occurred from the excessive heat in New York.

---

caroubiers, des figuiers, des jujubiers, des raquettiers, des dattiers, des grenadiers, et toutes sortes d'arbres fruitiers distribués sans ordre, en [illegible] toute leur vigueur, achèvent d'orner et d'embellir ce bel ensemble."—Risso, Op. citat.

Hospital Reports.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief notes by Dr. Tonge.)

Paraplegia. — W. B., æt. 32, pressman. Admitted November 12; discharged December 17. In hospital 35 days. *Unrelieved.* Never had syphilis, or any bad illness; had a fit 2 years ago, convulsions and delirium, followed by impairment of memory, pain in back, and loss of strength, 17 months; partial paraplegia 6 months. On admission can walk a little; left arm and leg weaker than right arm and leg, no loss of sensation; pain in occiput and down spine; tenderness of lower dorsal region of spine; feeling of constriction round upper part of abdomen; micturition difficult; bowels sluggish; pulse 80.

Iodide of potassium, liq. cinchonæ, and bicarbonate of potass; then dilute muriatic acid, chloric ether, quassia and quinine; tepid shower baths; wet packing.

Cerebral Hæmorrhage.—Anne W., æt. 48, charwoman. Admitted February 15. *Died* on February 17. In hospital 2 days. Was in King's College Hospital for epilepsy in May 1863. Previously epileptic 6 years. Last fit one month ago. Was suddenly seized with convulsions on morning of admission. On admission, comatose; breathing stertorous; pupils contracted, and insensible to light; no palsy or rigidity of limbs, but reflex actions more easily excited in right limbs than in left; pulse 146; respiration 50. Coma deepened, and she died on 17th.

Post-mortem.—Calvarium very thick and adherent; blood extravasated over upper surface of right hemisphere, cerebellum, and base of brain; left corpus striatum, and optic thalamus, broken down by effused blood, which filled left ventricle; small clot in right ventricle; arteries at brain's base, and mitral and aortic valves atheromatous.

Croton oil; two enemata of turpentine and castor oil.

Hemiplegia.—Harriet P., æt. 51. Admitted October 5; discharged December 3. In hospital 59 days. *Unrelieved.* Had a fit four months ago, with loss of speech and loss of power in arms. On admission semi-stupid, speechless, has lost memory; complete left hemiplegia; sensation impaired; reflex action in leg diminished; arm rigid; face much drawn to the right; tongue put out to the left; fæces and urine passed under her; pulse 80. Partial recovery of speech and power in left arm.

Aromatic spts. of ammonia and camphor water (29 days); then chloric ether and sesquichloride of iron; cod liver oil; brandy.

Softening of Brain—Chronic Renal Disease.—Sarah H., æt. 34. Admitted September 16. *Died* on Sept. 17. In hospital one day. Intemperate. Admitted in a semi-conscious rambling state, which had lasted since the middle of the previous night. No convulsions; some rigidity of right arm, and palsy of right buccinator; pupils dilated and insensible.

Post-mortem.—Right corpus striatum, and part of optic thalamus, much softened, and of a red colour. Kidneys much contracted; surface very granular; combined weight 6 oz.

Oil croton, ♏iii.; e. l. to neck; enema of tr. serpent., sp. ammon. fœtid., and aq. on 17th.

Delirium Tremens.—J. S., æt. 30, law-writer. Admitted December 11; discharged December 20. In hospital 9 days. *Recovery.* Drinks much rum and water. On the 8th and 9th, worked all night and drank more than usual. Delirious and tremulous on 10th; spectral illusions. Slept on night of 11th; rational and free from tremor on 12th.

Tinct. opii ♏xlv.; brandy 6 oz.

Delirium Tremens.—Sarah L., æt. 33, needlewoman. Admitted October 7; discharged November 5. In hospital 29 days. *Recovery.* Has drunk freely during last 3 months. Previously ill 14 days; tremors; restlessness; spectral illusions, and loss of appetite. On admission very tremulous, excited, and incoherent; with flushed face, creamy tongue, and pulse 96. Six days later sleeps well; no incoherence. Five days later free from tremor.

Carbonate of ammonia, chloric ether, and liq. ammoniæ acetatis (5 days); then iodide of potassium and quassia. Pulv. ipecac. co. gr. x. on 8th.

Delirium Tremens.—J. C., æt. 38, tobacco-manufacturer. Admitted June 24; *died* on June 28. In hospital 4 days. Had been drinking more than usual. Previously ill 3 days. Very tremulous; much sweating; sleeplessness; spectra; tongue furred; slight bronchitis; became violent; died suddenly.

Post-mortem.—Heart pale, flabby, and loaded with fat; considerable opacity of arachnoid; slight excess of subarachnoid fluid.

Aromatic spts. of ammonia, and liq. ammon. acetatis. Tinct. opii (large doses); aperients.

Delirium Tremens.—C. A., æt. 51, lawyer's clerk. Admitted May 9; discharged May 23. In hospital 14 days. *Recovery.* Intemperate. Subject to attacks of tremor without (?) delirium. Pecuniary anxiety of late. Has drunk about 5 quarts porter daily for last 3 weeks, and eaten little solid food. Previously ill 4 days. Tremors, horrors, frightful dreams. Inclined to jump out of window on 5th day; violent and noisy on 11th, 12th, and 13th days.

Large doses of tinct. opii. Brandy and porter. Castor oil; aromatic spts. of ammonia.

Incipient Delirium Tremens.—J. S., æt. 42, laundress. Admitted June 21; discharged June 29. In hospital 8 days. *Recovery.* Since death of husband, 2 years ago, loss of memory, disturbed sleep, and constant dread of impending evil. Subject to headache. Previously ill three days. Anorexia, sleeplessness, and frightful dreams. Hysterical.

Aromatic spts. of ammonia and camphor mixture.

Chronic Delirium Tremens.—E. M., æt. 41, tailoress. Admitted June 13; discharged June 25. In hospital 12 days. *Recovery.* During last year, catamenia, bi-monthly and profuse. Family troubles. Previously ill one month. Disturbed sleep. Thoughts of suicide and killing her children. Some headache and confusion of thought; low spirits; bad appetite; furred tongue; frightful dreams; feeble pulse; occasional globus hystericus.

Opiates; quinine and sulphuric acid; castor oil.

Chronic Delirium Tremens.—E. M., æt. 42, tailoress. Admitted July 19; discharged August 6. In hospital 18 days. *Very much relieved.* Became worse after discharge from King's College Hospital. Now in much the same state as before. Slight hæmoptysis on day after admission. Some crepitation and increased vocal resonance under right clavicle.

Quinine and dilute sulphuric acid; then same with sulphate of iron; tinct. opii. ♏xxv. h.s.s.

Delirium Tremens.—S. M., æt. 25, servant. Admitted March 28; discharged April 11. In hospital 14 days. *Recovery.* Leucorrhœa 3 months. Vomiting and purging 14 days ago. Since then disturbed sleep; debility and headache. Pulse 124. Bowels confined.

Aromatic spts. of ammonia and chloric either. Tr. opii. ♏xxx. h.s.s.

CITY OF DUBLIN HOSPITAL.

TWO CASES OF CANCRUM ORIS,

Under the care of Mr. CROLY.

Case 1.—J. M'K., a boy aged 5 years, was brought by his mother for surgical relief. His health suffered materially of late, in consequence of successive attacks of whooping-cough, scarlatina, and measles. He lived in an unhealthy locality in this city. He presented an anæmic appearance. His *left* cheek was much swollen and shining; he cried from the pain, and very fœtid saliva dribbled from his mouth. The glands of the neck were enlarged. On opening his mouth an ashy grey-coloured slough was observed, extending from the angle of the mouth at the left side (and involving the lower lip) to behind the last molar tooth.

Treatment.—The diseased part having been dried with lint, a piece of soft wood, chewed at the end, dipped in strong muriatic acid, was freely applied to the entire slough. The teeth were protected by a piece of lint, saturated with olive oil. Chlorate of potash, in fifteen-grain doses, in decoction with tincture of bark, was directed to be taken three times a-day, and a chlorate of potash gargle to be used frequently. A liberal allowance of wine, and beef-tea was also prescribed. In two days, under this treatment, the slough became detached; the part assumed a healthy appearance, and the boy recovered quickly.

Case 2.—M. M'K., aged three years, *sister* of subject of preceding case, was similarly affected in the *right* cheek, but not so severely. The same treatment was adopted and with great benefit.

Remarks.—Mr. Croly explained that cancrum oris is a serious sequela of measles, occurring in delicate children who are ill-nourished and dwelling in unhealthy localities. The disease, he said, has been confounded with mercurial salivation, but may be easily diagnosed by the history of the case, and by the fact of cancrum oris attacking only *one* side of the mouth, whilst the sloughing caused by mercury occurs at *both* sides.

The treatment must be decided. Muriatic acid is a favourite and excellent application, and the internal administration of large doses of chlorate of potash in bark, with generous and stimulating diet, constitutes the proper treatment for this formidable disease.

The occurrence of the affection in two children of one family at the same time, is remarkable and worthy of notice. Noma pudendi, of which a case was recorded by Mr. Croly in a late hospital report, is an analogous disease, and requires the same line of treatment.

DR. STEEVENS' HOSPITAL.

CYSTIC BRONCHOCELE: RECOVERY.

UNDER THE CARE OF DR. M'DONNELL, F.R.S.

(Reported by R. L. SWAN, F.R.C.S.I., Resident Surgeon.)

JOHN TREONLY, æt. 35, a constable in the constabulary force, was admitted into Steevens' Hospital, November 2nd, 1867. About twelve months before, he noticed a slight enlargement in the situation of the thyroid body. This, at first, gave him no uneasiness, but as it gradually increased, the pressure of the stock caused him considerable annoyance. On examination, a tumour, somewhat larger than a billiard ball, was found occupying the middle line two inches above the sternum. The skin covering it was unchanged; fluctuation was distinct; there was no pain or local evidence of inflammation.

November 16.—The sac having been half emptied of a fluid resembling serum, one drachm of the tincture of iodine was injected.

17th.—Little or no inflammation produced; the tumour as large as before the abstraction of the fluid.

30th.—The sac having been completely emptied, two drachms of the tincture were injected.

December 1st.—The tumour is again filled with fluid; some tenderness and pain exists.

5th.—Some increase in size; the swelling has resumed its original painless character.

21st.—Having emptied the sac, four drachms of the tincture were now injected; inflammation, followed by suppuration, took place, and eventually, a perfect recovery. The patient was discharged, January 9th, 1868.

We have not frequent opportunities of seeing cystic goitre in this country. It is much commoner in central Europe. There is some difference of opinion as to the best mode of treating it. Hamburger, from extensive experience in Bohemia, recommends the seton as the safest and most efficacious means of curing this complaint. Patruban, on the other hand, considers Hamburger's method highly dangerous, and recommends incising and emptying the sac, and fastening the remaining portions of it to the integument. The plan adopted in this case seems to have received the sanction of most surgeons in this country. Taking into consideration the close proximity of the trachea, and other important organs, and the dangerous consequences that must ensue from a violent degree of inflammation being excited, it is evident that too much caution cannot be observed in the application of a remedy.

ACUTE INFLAMMATION OF THE THYROID BODY: RECOVERY.

James O'Neill, aged 37, a brass-moulder, was taken into hospital, April 30th, 1868. He had been under treatment for more than three years, suffering from syphilis in an advanced form, having had repeated attacks of inflammation of the periosteum of the frontal and parietal bones, for which he had been principally using the iodide of potassium, which he considered to have most power in checking the disease. He had likewise a continual hoarseness—the result of old laryngeal implication. While at work the day before admission, he noticed a soreness of the anterior portion of the neck, and on going home was seized with severe rigors, nausea, and some difficulty of breathing. When admitted there was considerable inflammatory fever; tongue furred; pulse 120; there was some headache. On examining the thyroid body, both lobes were found symmetrically enlarged, painful, very hard, and sensitive to the touch. The integument covering the organ, was œdematous and redder than the surrounding skin.

Ordered—the hospital diaphoretic mixture.

May 4th.—The inflammatory symptoms have in a great degree subsided. As the man could not bear a continuance of lowering measures, a tonic line of treatment was now adopted.

Ordered—bark and nourishing diet.

7th.—Feeling now as well as usual, the patient left the hospital. The thyroid body has become reduced to its normal size.

Acute inflammation of the thyroid body is universally admitted to be an uncommon affection. This fact will probably account for the difference of opinion that exists as to the class of individuals most liable to be attacked. Dr. Macleod in his outlines of surgical diagnosis, states that it usually occurs in a healthy person; while Dr. Copland asserts that it arises spontaneously in this organ in scrofulous persons only. The rapidity of the attack; high constitutional disturbance; and equally rapid subsidence of the inflammation are remarkable.

In reviewing the case the interesting question arises—If the pathological conditions of the organ were more completely investigated, how much further light might be thrown on its physiological purposes, now confessedly obscure? It is well to add that the patient himself attributed his attack to the inhalation of the dust raised in scraping and cleaning the inside of a copper boiler, at which he had been employed for some days before his illness came on.

◆

Literature.

ELEMENTS OF CHEMISTRY.[1]

THIS issue may be considered as completing an edition of this important work—"Part III., Organic Chemistry," 3rd edition, published in 1866; and "Part I., Chemical Physics," 4th edition, published in 1867. The only discrepancy manifested is, that in the organic chemistry of 1866, the author had not entirely discarded the old notation, and barred symbols were, therefore, used to distinguish the new equivalents from the old.

In the present volume there is little to report upon as new, the general characteristics of the book are the same, if we except some changes in the nomenclature, and some valuable additions occasionally to the text.

---

[1] Elements of Chemistry. By William Allen Miller, M.D. Part II., Inorganic Chemistry. 4th Edition. London: Longmans, Green; Reader and Dyer. 1868.

The author uses the term non-metallic elements in its substantive sense. Although the word non-metals is a better word than the decidedly erroneous one, metalloid, we cannot see that such terms are desirable additions to our chemical vocabulary.

It is, in our opinion, almost time to discard the division into non-metallic and metals entirely. It is quite arbitrary, and so ill-defined, that it may be an open question to which division many of the elements belong. Much better would it be only to use the term "metals" in its practical sense, as applied only to those (precious or otherwise) which are used as such, and only when spoken of in connection with their uses in the arts. To found a scientific division of the elements upon such ill-defined physical properties is straining at nihility.

At page 273, Frankland's ideas upon the luminosity of flame are explained. As that gentleman has been lecturing lately at the Royal Institution upon this subject, it possesses a little popular interest. Dr. Frankland thinks that the phenomenon is not so much a matter of solid incandescent particles as a matter of pressure. Thus in an experiment with hydro-carbon flames, for each diminution of one inch of mercury, gave 5·1 less light, the diminution of light being directly as the diminution of pressure.

The description of glass-making and metallurgical processes are very complete and full.

At page 457 is given what is said to be a more delicate test for ammonia than Nessler's, a matter of some importance, now that so much attention is paid to the presence of that substance in potable waters.

Not by any means the least important part of this valuable volume will be found in the latter chapters viz., chapter xx., "On some circumstances which modify the operations of chemical attraction." The substance of this chapter is given in Part I., Chemical Physics, but is here treated in a more extended form. This chapter treats of the influence of cohesion, adhesion, and elasticity, influence of mass, heat and cold, on chemical attraction. Chapter xxi., a most interesting chapter upon the combining numbers of the elements, and the data for determining those numbers.

WATTS' DICTIONARY OF CHEMISTRY.[1]

We congratulate the author on the conclusion of his labours, the public upon the addition of the most important work for chemical reference extant in our language, and the publishers upon the successful completion of a most felicitous undertaking. The favourable augury with which the advent of the dictionary was received, has been thoroughly endorsed by general acclamation, as the book has proceeded through its course of publication, a period of some seven or eight years.

The editor, instead of getting tired of his work, evidently warmed into it, for, if a preference could be given to any of the volumes, it would be to those published in 1867 and 1868, which exhibit a greater unity of arrangement. We can well understand the feeling that animated the London chemists when they invited Mr. Watts to a banquet, commemorative of the completion of this work.

Not that the dictionary is perfect. There are many weak points which were almost from the mode of issue, &c., unavoidable, but if we were inclined to point out these shortcomings, it would be of no avail, for the author meets you half way, by alluding to them himself. If you read his own preface you have almost every important deficiency pointed out.

Mr. Watts has promised us an occasional supplement, by which he intends to keep the dictionary up in a measure with the progress of science. This plan, which was suggested some twelve months since in THE MEDICAL PRESS AND CIRCULAR, is one which we sincerely hope Mr. Watts will carry out.

In rapid revision we may be able to give some faint idea of this work to such of the readers who have not seen the notices already given from time to time.

In the first volume the articles upon acids, amins, (compound ammonias), and alcohols, atomic volumes, atomic weights, chemical affinity and classification, written by the editor, Prof. Foster, and Dr. Odling, are monographs in the encyclopædian style, which are perfect essays in themselves, although the article "Atomic Weights" is hardly in keeping with other portions of the dictionary. The other important articles, of which especial mention may be made, are albumine, alkaloids, analysis, balance, beer, blood, blowpipe, bone, with tables of comparative analysis of bones belonging to different orders of the animal kingdom, and their composition per bone; cereals with tables of composition.

The minerals under their respective heads are given very completely in this and the other volumes, but seem to be chiefly compiled from Dana's great work.

The article on crystallagraphy, a subject so seldom practically understood by the chemist, is especially full, yet lucid. The next most important articles in this volume, are electricity and elthylene bases, the latter by Dr. Hofmann. After these come long and elaborate articles on digestion, chemical geology, rational formula, &c. Vol. 3 contains elaborate essays upon heat (138 pages), metallurgy, and light, the latter a most exhaustive treatise. The most important of the other long articles are, perhaps, animal nutrition (Vol. 4), and spectrum analysis (Vol. 5). C.R.C.T.

THE STOCKFEEDER'S MANUAL, &C.[1]

THE principles which should guide those who undertake the rearing of animals for the food of man, are most fully and clearly set forth in Prof. Cameron's work, which displays most accurate physiological as well as chemical knowledge. Several valuable analyses and directions for the detection of unsound food, are included in the book. Any of our rural friends whose spare time is sufficient to allow them to engage in stock-farming, should attentively study Dr. Cameron's manual.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 5, 1868.

THE 86TH REGIMENT AT THE MAURITIUS.

WE have good reason to believe that as regards the circumstances under which the "Royal County Down Regiment" was disembarked at the Mauritius, in opposition to the protest of the medical authorities there, it may be well to bear in mind the old adage of "the least said the soonest mended." No such cause of reticence, however, exists in reference to some of the other points connected with the medical history of the corps during its residence in that island. Undoubtedly had public considerations alone influenced all concerned, the more prudent plan would have been for the regiment to have returned to the Cape, instead of being landed at Port Louis, "in the thick of the malaria," as described by a correspondent on the spot, and when arrangements for their reception had not been made, although submitted two months and a-half before that time. As a result of this mistake, all who were thus exposed to the exciting causes of the fever from which they subsequently suffered, had become tainted with it before going to the out-stations to which they were afterwards sent, and where, during two months, all classes of the regiment continued to suffer from the malady. Fortunately, the death-rate was inconsiderable, only five fatal cases having happened among the soldiers, although the number of attacks have been very great, and the amount of non-efficiency by secondary affections of the liver and spleen, such as is familiar to Medical Officers serving with our troops in India, and notably at the station of Peshawur.

[1] Watts' Dictionary of Chemistry. 5 Vols. London: Longmans, Green, and Co. 1868.

[1] The Stockfeeder's Manual, &c. By C. A. Cameron, M.D., Professor of Hygiene, R.C.S. London: Cassell, and all Booksellers.

It is to be feared that some accounts of the prevailing epidemic which have reached this country, have been somewhat *sensational* in their character, especially those animadverting upon the supposed deficiency of some necessary medicines wherewith to treat it. We have it on authority not to be questioned, that an ample supply of quinine was brought from the Cape with the regiment, and that no less than eighty pounds of that drug had by the principal Medical Officer in the island been accumulated from various places, as the Cape, Ceylon, and England, from which he was able to supply not only all requirements of the military, but of the civil also.

It is very satisfactory that whatever may have been the mismanagement on this occasion, not only is the medical department completely exonerated, but we know that had full operation been given to medical opinion, the 86th Regiment would now, in all probability, have been strong and efficient, and in one of the finest climates in which troops can serve.

ENGLISH POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

Last Friday afternoon the annual meeting of the Metropolitan Association of Poor-law Medical Men was held at Freemasons' Tavern, when, in pursuance of the aggregate meeting reported by us, the following resolution was adopted:—

"That the Metropolitan Poor-law Medical Officers' Association and the Poor-law Medical Reform Association be united, under the title of "The Poor-law Medical Officers' Association;" and that the Council consist equally of metropolitan and provincial members, and, if possible, of an equal number of workhouse and district medical officers of each class."

The consequence of this was of course that the meeting resolved itself into the first meeting of the new society which will henceforth be called the Poor-law Medical Officers' Association.

This new society, combined of old and tried, though divergent parts, will become entitled to some £60, being the balance in the hands of the greatest of poor-law reformers, Richard Griffin, of Weymouth, who was treasurer to the old Reform Society.

We have much pleasure in chronicling the fact of so much unanimity prevailing that it has been found easy to carry out the idea we have frequently urged, of making the society that has done so much the organ of poor-law doctors, not only in London, but throughout the provinces.

It was stated that some 300 officers had already given in their adhesion, so that with a fair balance at the bankers, and a good roll of members, a beginning has been made which may lead to much.

We append the last report of the Council of the Metropolitan Society, as adopted at the meeting.

ANNUAL REPORT OF THE COUNCIL—JULY, 1868.

"In presenting their second annual report, it affords your Council much satisfaction to state that the Association has made great progress during the past year. The number of members has been nearly doubled, many provincial medical officers having joined as associates. The cash balance in hand, after payment of all claims, amounts to about £25.

It having been frequently suggested that the Association should extend the field of its operations and admit to the right of membership all medical officers residing in England and Wales, your Council have had under consideration for some months past the propriety of submitting, at the annual meeting, a proposition to alter the title of the Association by omitting the prefix 'Metropolitan.' They do not doubt that such a proposition would have been received with favour at any time, but much more so at the present time after the very successful meeting of London and provincial officers, held last month, under the chairmanship of W. J. Clement, Esq., M.P., F.R.C.S. At that great meeting—great by reason of the numbers, intelligence, and unanimity of those who attended it, many of whom came from distant parts of the kingdom—a strong and general wish to this effect was expressed. The actual proposition in favour of union emanated from Mr. Richard Griffin, of Weymouth, who stated in his letter to the chairman, that if it was carried he should feel justified in handing over the balance of £60, of the funds of the Poor-law Medical Reform Society, remaining in his hands as chairman. The only condition made by Mr. Griffin—a perfectly fair and natural one—was 'that the Council should consist of an equal number of metropolitan and provincial members, chosen equally, if possible, from workhouse and district medical officers.' A resotion to this effect was moved by Dr. R. Waudby Griffin, of Southampton, seconded by Dr. Robert Fowler, of London, and carried by acclamation.

"Your Council have much pleasure in recommending the Association to accept the proposition to alter the title to 'The Poor-law Medical Officers' Association.' They have very carefully gone through the existing rules, and having been favoured with suggestions by numerous provincial medical officers, they have drawn up a new code, suitable to the altered circumstances of the Association, which will be submitted for consideration and approval at the annual meeting. As the rules are in the hands of the members it is unnecessary to recapitulate them here, but your Council may state that they have determined, after careful consideration and with the approval of the majority of their provincial correspondents, to recommend a reduction in the amount of the annual subscription. This they propose to fix at a very moderate sum, in the hope thereby of seeing the ranks swelled by very large additions of new members.

"It is, above all things, desirable that the Association should be established on the widest possible basis, for the just demands of so important a body as the medical officers—between 3000 and 4000 in number—must be listened to if expressed with firmness and unanimity.

"Your Council also propose to enlarge the 'objects' to be attained, while restricting them more than heretofore to matters directly affecting the welfare and the interests of the medical officers. And there is good reason for this, because the best guarantee for the proper treatment of the sick poor lies in a contented state of the medical service, which can only be secured by a fair consideration and removal of admitted grievances. To obtain this end nothing would be more conducive than the 'establishment of a real (Poor-law) Board, with real meetings of responsible officers; and, inasmuch as medical affairs amount to a very large proportion of the total business of the office, the permanent chief of a properly constituted medical department ought to be a member of the Board with voting power.'—*Poor-law Chronicle*, July 7, 1868. That events are tending towards the formation of such a Board may be fairly inferred from the action taken by the Lords' select committee on the Poor Relief Bill, which, by a vote (which left the President of the Poor-law Board in a minority of one) affirmed the principle that additional medical inspectors should be appointed. Your Council heartily approve this decision of the Lords, based, as it is, on enlightened public opinion, which the Association has helped to form. But they believe that the appointment of more inspectors merely would be but a single step in the right direction, as improved inspection would be of little avail if there were no such Board to receive the reports of the inspectors, to consider their suggestions, and, if necessary, enforce their recommendations. Your Council cannot but believe that it would be for the public interest that all the inspectors should meet regularly for the discussion and settlement of the various questions which arise, and go through the country on circuit at stated periods to inspect not merely the workhouse but the working of every department of the local administration of the Poor-laws in connection with the sick poor; and a lay and a medical inspector might very usefully make their circuit together, after the plan followed by the Commissioners in Lunacy. But the same inspector should not go twice consecutively over the same district. The system which attaches an inspector to a district for a large number of years is essentially faulty. It may enable him to earn the good will of local officials, but it affords a very poor security for the faithful discharge of duties which must always be onerous and, not seldom, painful or at least unpleasant.

"Your Council have been led to make these observations by a strong conviction that it is only by putting the whole system of poor-law management upon a sound footing that they can hope for a general removal or amelioration of the grievance under which the medical service now labour.

"Your Council have observed with satisfaction that the Poor-law Board have at length arrived at the opinion that uniformity in workhouse dietary is desirable. They have suggested a dietary for use in the metropolitan district which, however, has not been very favourably received. This, however, cannot be altogether a matter of surprise, as the dietary is open to some objections, and it would not be desirable to establish it without important modifications based on the dietary long since drawn up by your Association. The dietary appears, however, to be based upon that recommended by the Association, but the variations from that dietary are not improvements.

"As this will probably be the last report issued by your present Council, it may not be out of place to express a hope that the proceedings of the enlarged Association may be marked by the same unanimity and kindly feeling which have distinguished those of the Metropolitan Association. Meetings like these bring together many men with identical interests and many feelings in common, who otherwise would have scarcely any opportunity of becoming acquainted with one another. From such intercourse many good results must follow, even if material interests are not advanced with desirable rapidity. Not the least of them is the establishment of an agreement as to the wants and wishes of the service; and this is very necessary, for the medical officers must make up their own minds upon questions affecting their status and remuneration before they can hope to make an impression upon public opinion and secure a full concession of their claims.

"Your Council would fain believe that the meetings held during the last two years have helped somewhat in this direction. They have assisted in enlightening public opinion on various points connected with the service, and they have been well supported by the press. Much evidence of sympathy with the medical officers has been elicited in quarters where it cannot fail to be of use under a new Parliament. The Metropolitan Poor-law Medical Officers' Association has won for itself a fair position, which it yields very willingly to its successor, in the firm conviction that by means of larger numbers and more extended influence that position will not only be maintained but improved, and that the good work will be carried on to a successful and speedy issue."

MEDICAL DEGREES IN THE U.S. OF AMERICA.

There is a good deal of ignorance prevalent among us about the medical qualifications of our transatlantic brethren, and as we have recently had the pleasure of inspecting what our readers will doubtless consider a remarkable document, we shall make a few observations on the genuine, as distinguished from the humbug degrees, which are openly given—even sometimes under legal sanction—in the United States.

In the first place, we must remember that there is no real difficulty in almost any American medical school obtaining the power of conferring the sole necessary qualification, that of M.D. "The New York Homœopathic Medical College," and many others of like kind, have this right; and are, legally speaking, on perfectly equal terms with the respectable and really learned institutions which confer medical degrees on the first class of American physicians, whose representatives, or members, we so often have the pleasure of welcoming to our houses in the mother country; and who are professionally inferior to no medical men in the world.

In the United States the assumption of the title of M.D. without legal right is attended by no legal penalty. Any one can style himself captain, or colonel there, and so he may adopt the more learned professional title if he think fit.

But, apart from this facility in becoming, or assuming to have become, an M.D., it may be stated that a few years ago there were in the United States no less than thirty-seven medical schools, each of which conferred the degree of M.D.

Some time ago Sir Dominic Corrigan astonished the medical world by telling them that there was then an agent in these countries disposing of medical degrees to needy or illiterate candidates, without examination, and for a trifling consideration. His statement was indignantly denied, but he proved his case without any doubt.

As an instance of a certain class of "degrees" which are attempted to be foisted into these kingdoms under any but true pretences, we shall give *verbatim, literatim, et punctatim*, a copy of one which lately came under our observation.

It was forwarded by its owner (we understand) to one of our most respectable and time-honoured medical corporations as a *bona-fide* qualification, on the ground of which the owner sought for admission to examination for a medical license. At the same time a similar application was made by an M.D. of the College of Physicians and Surgeons of New York—one of the oldest and most respectable of the American licensing bodies; the former application was refused, while the latter was granted.

Herewith we give the document above referred to, merely suppresing the name of the candidate, with the names of those who signed it, and the date:—

"To all men greeting.

"Be it known that the President on behalf of the Trustees, and we, the Faculty of the Eclectic Medical College of Pennsylvania, incorporated by an Act of General Assemby, of the Commonwealth of Pennsylvania,

do hereby testify, that ————

Having made suitable proficiency in the preliminary branches of education as preparatory to the study of the Medical Profession, and devoted the term of three years to the study of the several departments of Medical Science, under the tuition of a competent Medical Preceptor, and having attended two full courses of Medical Lectures, and passed a successful examination in each department of study before us, the Professors of the College; therefore in consideration of his qualifications for the duties and responsibilities of the Profession, and by virtue of the power vested in us by the Commonwealth of Pennsylvania, we do hereby confer upon the said ———— the degree of Doctor of Medicine, thereby granting and conceding unto him all the Rights, Privileges, and Immunities belonging to that degree here and elsewhere. We also recommend him to the confidence and patronage of the public.

"In Witness Whereof, we have caused to be affixed our corporate Seal to this Diploma, and subscribed our names to the same.

"Given at the College Hall at Philadelphia, on the —— day of April, A.D. 186—."

At the bottom of this document was a grand seal, on the margin of which were the words—"Eclectic Medical College of Pennsylvania. Incorporated 1850." In the centre, and amidst a "glory," was the potential term "Eclectic;" and around it, outside the glory, but inside the marginal legend were these awful derivatives—

"Chromo-thermal," "Electropathy," "Hydropathy," "Allopathy," "Thomsonism," and "Botanic." Close beside these were recorded the words "Truth," "Nature," and "Wisdom," admirable principles indeed, on which, doubtless, "the Eclectic Medical College of Pennsylvania" professed to conduct its operations.

THE MEDICAL ELEMENT IN PARLIAMENT.

We have so often urged the absolute necessity of more medical men finding access to the House of Commons that the subject is becoming almost trite. Now, that new names have been brought forward, and that the Parliament has actually, so to say, expired, we may, perhaps, again return to a question so full of importance to the profession. We can most heartily wish all our professional brethren success whenever they may seek a seat, and only regret that division is likely, occasionaly, to prevent this.

It is certainly to be deprecated that the medical interest should be recklessly divided, and when one medical man has a prospect of support, it is a pity to set up another. The first must have deserved well for the courage he evinced in coming forward. The second may spoil his chance without winning.

Even if won, the victory snatched from a professional brother is of less value than the defeat endured by those who assert the principle.

The importance of medical men being in the House is just now so much thought about, that we add the remarks of Dr. Mapother on the subject in his Essay, which won the first Carmichael Prize :—

"It must be admitted on all hands that the importance of the profession of medicine is not fully recognised, many causes having contributed to degrade it from the position it should occupy. Foremost among them is the fact, that the public, uninformed of the functions of the human body, have imperfect means of judging of the comparative merits of those who treat their derangement. The superficial and boasting practitioner is many a time the favourite with the vulgar, to whom the honourable and well-informed practitioner will offer neither flattery nor false hopes. Another, is the absence of just rewards, such as elevated positions in the State, for its most distinguished promoters, which would stimulate the talented and refined to adopt it as their calling. It is almost universally acknowledged that the educated and enlightened classes are not adequately represented in our country's senate. It was, however, confidently hoped that this anomalous state of things would cease as soon as the Reform Bill became law, but that measure only enacted that the London University should have a representative, and it is to be feared that he will not be chosen from the medical profession. No impartial man could then deny the importance of having members of the medical profession, who could there be consulted on the numerous questions relating to public health to be discussed. The other learned professions are most amply represented in both Upper and Lower Houses; for instance, over 100 members of Parliament are practising barristers, and no just reason ever has, or probably can be, adduced why medicine should not enjoy similar invaluable privileges. The main objections urged to medical representation in parliament is, that no profession or calling is directly represented ; be that as it may, the clerical and legal professions, and commercial and other callings, have very many advocates there. But if the profession is not to have special members of parliament, the licensing bodies may fairly seek the privileges which the universities have so long enjoyed, and if they amalgamated, as shall be hereafter advocated, such a just concession could not be long denied. Licentiates of five years standing might share the franchise with fellows of the colleges.

"It may be said that the university representatives represent medical men, but how few of the constituents of Oxford, Cambridge, and Dublin, are doctors of medicine, and when was a member of the profession chosen? Even in the London University, where half the constituency is medical, and where half the places on the Senate and Committee of Convocation have been bestowed on the profession, there is, it appears, no chance for a medical representative. The inability of medical men to make themselves heard in parliament, renders them liable to have their interests, which are as well, in most vital respects, the interests of every man, woman, or child, overlooked or despised. The intimate knowledge of mankind, psychical as well as corporeal, which they must acquire, would render their opinions valuable and their decisions judicious. It may be objected that, as medical men derive their incomes from the active exercise of the profession, they could not afford to relinquish such emoluments. This is assuredly fallacious, as many, distinguished and disinterested, would submit to such pecuniary sacrifice for so grand an opportunity of administering to the public good, and a leader in Dublin has already volunteered. Besides, there are some positions in the legislature (and there should be more) where their services could be recompensed. In the United States, many high senatorial and other offices in the government are filled by medical men ; for example, Dr. Sheldon was Speaker of the House of Assembly. On the Continent, likewise, medical men frequently fill representative positions—*e.g.*, Virchow. The great Haller, whose mind had undergone a very appropriate course of training for such duties, was the originator of many legislative and social improvements in Switzerland. As the sittings at Westminster take place at night, and for but a short period of the year, many London practitioners, who now reside in the country, during night, might attend with but little personal or pecuniary sacrifice. If precedent be asked for, we point to Radcliffe, the greatest benefactor of Oxford, Friend, and Mead, who all served their country in this position. There are at present three retired medical men in Parliament, Sir John Gray, Dr. Brady, and Mr. Vanderbyl ; and one practised surgeon, Mr. Clement. It is much to be regretted that the candidature of such distinguished members of our profession as Sir Charles Locock and Mr. Mitchell Henry has been unsuccessful. The latter gentleman canvassed Manchester in November last, and many of the medical men gave him energetic support—others declared that they preferred to follow party considerations.

"It is unpleasant to have to record that efforts were made some years ago by one of the largest medical corporations against presenting a petition to the Crown for Parliamentary representation. How different was the course the profession in Dublin adopted, the influential demonstration in Morrison's Hotel during June, 1841, exhibits ; and since then many fellows of the College of Surgeons, and foremost among them, Dr. Mackesy, have urged the matter. Acts of Parliament making has been heretofore regarded as the exclusive province of the politician and the lawyer, but many of them concerning the duties of medical men indicate the want of intelligent supervision which our profession alone could give. The glaring defect of our system of legislation is, that fragmentary measures called by some passing necessity or temporary alarm are enacted ; the Act for Controlling the Sale of Arsenic and the Bill for the Prevention of Glanders 'may be taken as examples, from which it might be inferred that there were no other poisons or no other contagion to be guarded against.'"

◆

Notes on Current Topics.

Figures not Fears.

Perhaps it is not to be wondered at, considering the long continuance of the hot weather, the absence of rain, and the consequent parched condition of the country, that serious apprehensions should have been entertained lest cholera might become epidemic amongst us this summer. There is cause, however, for congratulation, on receiving the Quarterly Returns of the Registrar-General, to find that at present such fears are unfounded. From a reference to his figures, registering the deaths occasioned by the prevailing epidemics throughout the kingdom, it will be seen that, in upwards of thirty-five places, not a single death from cholera is recorded. There may have been some few cases since, but not sufficient at present to cause any serious alarm.

The Public Health.

The following items are taken from the weekly return of the Registrar-General :—

"In the week that ended on July 25, 4384 births and 4050 deaths were registered in London and in 13 other large towns of the United Kingdom. The annual rate of mortality was 33 per 1000 persons living. The annual rate of mortality last week was 31 per 1000 in London, 22 in Edinburgh, and 23 in Dublin; 25 in Bristol, 38 in Birmingham, 37 in Liverpool, 40 in Manchester, 35 in Salford, 39 in Sheffield, 40 in Bradford, 35 in Leeds, 34 in Hull, 26 in Newcastle-upon-Tyne, and 37 in Glasgow. The rate in Vienna was 29 per 1000 during the week ending the 18th inst., when the mean temperature was 0·9 Fahrenheit higher than in the same week in London, where the rate was 27. The mortality from diarrhœa showed a further increase during last week in nearly all the large English towns, and was at the annual rate of 4 per 1000 in Newcastle-upon-Tyne, 6 in Bristol, 7 in London, 9 in Liverpool and Sheffield, 10 in Manchester and Salford, 11 in Hull, 12 in Leeds, and, highest, 14 per 1000 in Birmingham. In London the temperature in the shade rose to 96·6 deg. Fahrenheit, and the mean temperature of the week was 69·2 deg.; but there was no approach to these high temperatures in the other towns, the highest recorded in the shade being 91·6 deg., and the highest mean of the week 64·4 deg., both in Sheffield. It will be observed that in the English towns the lowest mortality from diarrhœa occurred in Newcastle, where the mean temperature of the week was only 60·3 deg., and lower than in any of the other towns. The deaths of 945 males and 940 females, in all 1885 persons, were registered in London during the week. It was the thirtieth week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1575. The deaths in the present return exceed by 310 the estimated amount, and are more by 243 than the number recorded in the preceding week. The deaths from zymotic diseases were 800, the corrected average number being 631. Seven deaths from small-pox, 35 from measles, 47 from scarlatina, 10 from diphtheria, 45 from whooping-cough, and 57 from typhus were registered. Fifty-eight deaths by choleraic diarrhœa or summer cholera were registered in the week; 38 were children under one year of age, eight aged one year, one aged three years, and two aged five years. Four hundred and forty-two persons died of diarrhœa, of whom 353 were children under one year of age, 49 were one year and less than two years, and 23 were of persons aged 20 years and upwards. The mortality from diarrhœa and choleraic diarrhœa or cholera differs little in the London waterfields. Eleven persons died of sunstroke. At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·969 in. The barometrical reading increased from 29·83 in. at the beginning of the week to 29·94 in. by 9 A.M. on Monday, July 20; decreased to 29·86 in. by 3 P.M. on the same day; increased to 29·93 in. by 9 A.M. on Tuesday, July 21; decreased to 29·78 in. by 3 P.M. on Wednesday, July 22; increased to 30·25 in. by 9 A.M. on Friday, July 24, and decreased to 30·03 in. by the end of the week. The mean temperature of the air in the week was 69·2 deg., which is 7·6 deg. above the average of the same week in 50 years (as determined by Mr. Glaisher). The highest day temperature was 96·6 deg., on Wednesday, July 22. The lowest night temperature was 50·9 deg., on Friday, July 24. The entire range of temperature in the week was, therefore, 45·7 deg. On Wednesday, July 22, the *maximum* temperature of the air observed—viz., 96·6 deg., is a higher value than has been recorded at the Royal Observatory as far back as authentic record extends, and the mean temperature for the day, 77·9 deg., has only been exceeded on the following occasions:—On the 24th of July, 1818, when the mean temperature was 79·2 deg., and on the 15th, 18th, and 19th of July, in the year 1825, when the mean temperatures were respectively 79·1 deg., 78·2 deg., and 78·6 deg. The mean of the highest temperatures of the water of the Thames was 70·7 deg.; that of the lowest was 70·2 deg. The air has been dry. The difference between the mean dew point temperature and air temperature was 15·3 deg. The mean degree of humidity of the air was 59, and on two days—Monday and Wednesday—it was as low as 49, complete saturation being represented by 100. Rain fell only on Wednesday to the amount of 0·01 in. The general direction of the wind was variable. Ozone was observed on every day except Sunday and Friday. According to a return furnished by the engineer of the Metropolitan Board of Works the average daily quantity of sewage pumped into the River Thames at the Southern Outfall Works, Crossness, was 45,822,141 gallons, or 208,191 cubic metres, equivalent to about as many tons by weight."

Lecture.

THE USE AND ABUSE OF "STIMULANTS."

By W. JACKSON CUMMINS, M.D.,

PHYSICIAN TO THE CORK SOUTH INFIRMARY AND COUNTY GENERAL HOSPITAL, EX-PRESIDENT CORK MEDICAL SOCIETY, ETC.

(A Lecture delivered before the "Cork Young Men's Association," January 7th, 1868.)

MR. PRESIDENT, LADIES, AND GENTLEMEN—The subject under our notice this evening—the Use and Abuse of Stimulants—is a grave one. The more I have thought about it, the more deeply have I become impressed with its vast importance, and with the responsibility of my position here as its exponent.

If the use of alcohol were forbidden in any part of the inspired pages, there would be an end to all argument on its behalf, even on the plea of urgent necessity, for the act of disobedience would in itself constitute it a sin, which would take its place side by side with murder, lying, stealing, and other breaches of the commandments of God; but after careful study, I am unable to find that any part of the inspired record can be legitimately strained into condemnation of the "use" of stimulants, although their "abuse" is denounced in no measured terms in both Old and New Testaments.

The sin lies in the abuse; and just as eating may degenerate into gluttony, or love into sensuality and idolatry, so may the use of both moral and physical stimulants, lawful in themselves, pass on into an excess which unfits for the responsible duties of life.

We must not, however, argue against the use of anything because it may be abused, and herein lies the chief difficulty of combating the majority of sins into which mankind is prone to fall; for it is not always easy to draw the line of demarcation between use and abuse—a difficulty which is increased in the case of alcohol, by its different effects upon different constitutions, and by the treacherous tolerance of its immediate effects arising out of habit.

It has been truly said that "if[1] alcohol were unknown, half the sin and three parts of the poverty and unhappiness in this world would disappear;" and if this be admitted, as I think it must be, by the most enthusiastic advocate of stimulants, no question of the day presses more urgently on the attention of the political economist, the statesman, the physician, the philanthropist, and the Christian minister; bearing, as it does, upon the social, political, and physical condition of man in the present, and upon the eternity for which this life is only a period of probation.

Alcoholic abuse is a monster evil which degrades and enslaves mankind, and limits human progress. It has been stated that[2] 60,000 lives are annually lost in Great Britain through its direct or indirect effects, and this terrible mortality is the least part of the evil which results to the nation from its favourite vice; for the moral and social effects of bad example, misery, and want, and still more, the impaired mental and physical condition handed down to posterity from generation to generation effect a degeneracy and degradation in the population which cannot be measured by figures.

---

[1] "Parkes on Hygiene."
[2] "Alcohol, its Place and Power." By Professor Millar.

The vice of alcoholic abuse is[1] hereditarily transmissible and often leads to[2] insanity after one or two generations.

The child of a drunkard is generally a dipsomaniæ by inheritance, his grandchild may inherit a tendency to epilepsy and insanity, while his great grandchild is liable to be an idiot, brutalized and destroyed by no fault of his own.[3] The sins of fathers have thus been visited on their children to the third and fourth generation, and it is not easy to say how many a noble race has thus died out, or how many an historic name has thus become extinct.

Most of the great sewers which drain the offscourings of mankind towards jails, workhouses, and hospitals—the cesspools, as they have been called, of humanity—are connected in one part or other of their course with strong drink, for crime, poverty, and disease follow hard and fast upon the footsteps of intemperance. Can we wonder then that—to use the words of a late author[4]—"Divines have preached, legislature has enacted laws, sanitary philosophers and physicians have written, taught, and practised; temperance societies have laid down rules and administered pledges;" . . . "orators and oratresses have thundered;" . . . "parents have whispered words of caution to the erring son;" . . . have 'commanded, threatened, punished,' and as a last resource, prayed by his love for them, by his fear of disgrace, by his danger of losing reputation, by all his hopes for this world and the next, to give up the cursed indulgence." To all this I may add that even judges on the bench have, from time to time, reasoned with juvenile criminals, and earnestly endeavoured to put down this vice which limits our national greatness, brutalises our population, and threatens our institutions, and the only wonder is that even more has not been attempted, for the magnitude of the evil calls, trumpet-tongued, upon philanthropists to exert themselves.

When a physician is called to prescribe for a disease, he first sets himself to ascertain, if possible, the cause of the symptoms presented by his patient, knowing that, as long as it continues in operation, he can do little more than palliate; just so, in seeking to remove a social evil, it is incumbent on us to seek out its cause.

Now those who are anxious to remove the great evil of alcoholic abuse, generally not satisfied with attributing it to habit growing out of the drinking customs of the people, and to a certain extent they are right, but would it not be better to go a step further back, and ascertain, if possible, the cause or causes of the drinking customs themselves?

It shall be my endeavour to do this, and I think I shall be able to show that they originate in our national character, and are closely connected with our institutions. But it may be said, and said truly, that the taste for wine and strong drink long preceded the Anglo-Saxon race, and the sources of its national intemperance, that the juice of the grape is intertwined with the earliest records and traditions, with the poetry and history of mankind, from its infancy to the present day.

Father Noah, we are told, had some prescience of sanitary law, and disdained to drink water because it contained organic impurity.[5] The pretty German legend tells us that "an angel visiting the earth some time after the deluge, found the patriarch sitting at noon in the shadow of a fig-tree, looking very disconsolate. The angel inquired the cause of his grief. Noah replied 'that he was thirsty, and had nothing to drink.' 'Nothing to drink'! replied the angel. 'Look around! Do not the rains fall, and the rivers run, and is there not a spring of water bubbling up at thy cottage-door?' 'It is true,' replied Noah, smiting his breast, 'that there is abundance of water in which thy servant can bathe; but, alas! when I think of the multitude of strong men, of beautiful women, and of innocent children, and the countless hosts of animals that were drowned in the flood, the idea of water becomes distasteful, and my lips refuse to drink.' 'There is reason in what thou sayest,' replied the angel, and spreading his snow-white wings, he flew up to heaven swift as a lightning-flash; and while the eyes of Noah were still dazzled with the brightness of his presence, returned with some stocks of the vine, which he taught the grateful patriarch how to plant and tend, and when the fruit was ripe, to press it into wine. This," says the story, "was the source of all the beneficent and benevolent drinks which the world owes to the grape."

It is true that although the Anglo-Saxon race has developed intemperance into a master-passion, there have been drinking-customs from the very earliest times, and it is also true that their increase has often been coeval with the downfall of great dynasties. Nor is it to be wondered at that strong drink should have been enjoyed among all nations and at all times, for the sources of human imperfection and human exhaustion commenced at the fall, when mankind shared the curse pronounced on creation, and learned that "in the sweat of his brow he should eat bread."

There was a time when our first parents lived in a condition of peace and contentment, surrounded by everything "pleasant to the eye, and good for food." The fresh, pure atmosphere of the virgin earth was untainted by the corruption of death; the spring, clear and sparkling, was presented to them in all its native purity and freedom from the germs of disease. Thus their perfect vitality was stimulated, and thus was the warm and well-nourished blood kept circulating with vigour in its proper channels. Conscious of no exhaustion after the light duties of each day, they lay down amid earth's choicest gifts to enjoy calm and undisturbed repose, and awake, free from anxiety and care, to derive nourishment from everything "good for food."

Let us pause and mark the contrast between man then and mankind now! Dwelling in a world subject to the curse, "thorns and thistles shall it bring forth," man himself labours under the edict which was thundered forth six thousand years ago, "In the sweat of thy brow shalt thou eat bread." The civilized earth has become a vast grave-yard, full of impurities, which taint its waters and load its atmosphere with pestilential vapours. Over-crowded cities and over-populated countries swarm with anxious and care-worn men and women, seeking—many of them in vain—for employment: suppliants for the work that "wins a meal," instead of being negotiators for a fair day's wages for a fair day's work—victims of excessive competition—ill-nourished and ill-requited—too often obliged to barter the hours of repose for less than the bare necessaries of life—existing rather than living—famishing, perhaps, and yet viewing other mortals wallowing in excess, and depriving themselves of the power to enjoy what their ample means can provide. Mental activity goes often hand in hand with physical decay, because the battle of life has been becoming harder and harder through succeeding generations. This is the age of mental and bodily activity, when men travel hundreds of miles in a few hours—when fortunes are made in a day, and lost in an hour—when news flashes in from the ends of the earth, creating a stir and a bustle, and a greed to be rich, and a national and individual competition, which keeps the energies of all who have anything to gain or to lose in a constant whirl of excitement—high-pressure is placed on all classes of society, and even the rising generation has learned to live fast. Like a thorough-bred charger, champing the bit and pawing the ground, with nostril dilated, and every vein swelling with restless impatience, the young man of the nineteenth century chafes at restraint, and when once let free starts into convulsive life, and too often drives headlong into a mad and unreflecting career.

Time *was* when "the morning stars sung together, and all the sons of God shouted for joy;" time *is* when "the whole creation groaneth and travelleth in pain together."

Time *was* when the high physical condition of man ministered to complete and perfect enjoyment; time *is* when imperfect development, inadequate nutrition, unnatural wear and tear, and uneasy and insufficient repose, go hand in hand to make man restless and impatient in the present —ever-craving for that which flies from his grasp.

What are the consequences of all these things?

First. Exhaustion has become a common condition of poor and rich.

Secondly. Stimulants are greedily sought for; and third, we must make rules for men as they are, and not as we would wish them to be.

The more we examine into this subject, the more are conclusions such as these, drawn from a superficial and general view, confirmed; for there is a strange power of adaptation to circumstances and surrounding conditions in man, and a physiological law by which a bent given in a certain direction in one generation, may be taken up by the next, and still further developed. This gradual adaptation to circumstances and conditions, progressing through many generations, is a means of imparting national peculiarities to masses of men, and a variety of constitutions to individuals. It is well-known that a temperate climate such as that of our favoured land, generates energy of character, and, as a natural consequence, the rise of great cities, and the development of industrial pursuits; these, in their turn, bring men together into monster communities, and produce that over-competition, over-speculation, and over-activity, which I have described.

It is scarcely credible to what an extent the human race is thus deteriorated, for the causes of decay and exhaustion in large cities are almost as numerous as the houses.[1] A committee of the Statistical Society of London, found in one lane in that modern Babylon only 90 bedsteads for 463 people, *i.e.*, about one bed for five persons, while some rooms had 22 persons living in them, and[2] Dr. Letheby, in reporting on the condition of the dwellings, says, that the air is not only "deficient in due proportion of oxygen, but contains three times the usual amount of carbonic acid," "blighting the existence of the rising population, rendering their hearts hopeless, their acts ruffianly and incestuous, and scattering the seeds for increase of crime."

The inhabitants of great cities are not as much overworked since the passing of the Factory Act in 1802 as they were before that time, when we are told, "the[3] laws of nature were wholly disregarded, and hundreds of the most helpless and sensitive of beings were annually used up by their remorseless task-masters, only to have their places filled by fresh victims."

It would take generations to efface the effect on masses of men still living, of such an overstrain upon the physical and mental powers of their ancestors. But even to this day the sources of exhaustion among our people, and especially among children in manufacturing towns are almost incredible.[4] The reports issued within the last few years (up to 1866) contain information which is most horrifying. Children of five, ten, and even three, are habitually overworked day and night, and denied the repose which exhausted nature requires; worked, too, sometimes in close confined atmospheres. Imagine girls of 10 years and upwards, in London and Manchester, kept at work 14, 15, and occasionally 18 hours a day, making artificial flowers in "dark" and "fœted" rooms; or poor little girls in metal manufactories, blowing a bellows 14 hours a day, standing on a platform to enable their little hands to reach the handle; girls of nine and ten wielding sledge-hammers and forging iron-chains from morning till night. Such are a few, and scarcely the worst, out of many such frightful instances contained in the reports I have alluded to.

No wonder these poor little creatures had never known the gladsome gaiety of a spring morning in the green fields, and could not tell what flowers, fishes, birds, rivers, mountains, or seas were.

No wonder that girls of 12 years old, when asked, "what is a violet?" replied that "it is a pretty bird;" that "a primrose is a red-rose;" that "a lilac is a bird," and were unable to tell whether a robin redbreast or an eagle were birds. Is it not horrible to think that children with such necessarily degenerate constitutions and minds, should become the fathers and mothers of our population?

"Do ye hear the children weeping, O my brothers,
Ere the sorrow comes with years?
They are leaning their young heads against their mothers,
And *that* cannot stop their tears.
The young lambs are bleating in the meadows,
The young birds are chirping in the nest,
The young fawns are playing with the shadows,
The young flowers are blooming towards the west—
But the young, young, children, O my brothers,
They are weeping bitterly.
They are weeping in the play-time of the others,
In the country of the free.

. . . .

'For oh!' say the children, 'we are weary,
And cannot run or leap,
If we cared for any meadows, it were merely to drop down in them, and sleep;
Our knees tremble sorely in the stooping,
We fall upon our faces trying to go;
And underneath our heavy eyelids drooping,
The reddest flower would look as pale as snow;
For all day we drag our burden, tiring
Through the coal-dark underground,
Or, all day we drive the wheels of iron,
In the factories round and round.'"[1]

Can we wonder that our people crave for anything which affords even temporary relief from such exhaustion as they acquire and inherit, and that drinking customs prevail?

The same reports tell also of dreadful overwork of children in agricultural districts, and we all know that want of proper nutriment is a fertile source of exhaustion among country labourers, especially in Ireland.

"The child is father to the man," and if a child is overworked or insufficiently sustained during the period when mind and body are undergoing development, its manhood will never acquire full vigour, its constitution will always be below par, and it will be ready to grasp at any stimulant which affords even a temporary and treacherous power to sustain the burden of life.

Hours might be spent in detailing the many sources of exhaustion among the lower orders of our overgrown cities which lead them to intemperance, but as the time at our disposal is brief, I shall pass on to the middle and upper classes, upon whom the great pressing necessity for toil through day and night does not fall.

But the Anglo-Saxon is the same in labour, in business, or in pleasure; his energy of character leads him to impose exorbitant exactions upon the poor material frame, and to deny it the repose which exhausted nature demands. Ambition lures on the middle class to exhaustion, to stimulation, and through it to premature decay, which is handed down to posterity, almost as surely as absolute necessity does the lower orders. Our statesmen, our divines, our physicians, our lawyers, our men of business, are continually exhausting their energies by over work, while both middle and upper classes follow pleasure and excitement with such eagerness, that exhaustion speedily follows and leads to "habitual tippling."

A late writer upon the increase of inebriety among the upper classes says[2]—"Almost everyone can plead medical advice as the beginning of the habit," but the truth is (as hinted in an article which I lately saw in one of the newspapers) that ambitious mothers, angling for earls, and viscounts, and eldest sons for their daughters, carry them, nothing loath, of course, to balls and routes, kettledrums, and dinner parties, night after night, with little intermission, through a London, Paris, and Brighton season—excitement after excitement—exertion after exertion—night turned into day from year's end to year's end. This sort of dissipation soon leads its victims to "galvanize" their exhausted energies into some show of vitality with champagne and sparkling Moselle, and when exhaustion has gone beyond a certain limit, to send for a doctor to sanction the use of brandy. This is, perhaps, prescribed at regular intervals, in moderate quantities, and to carry out the prescription accurately, the bottle is taken to the bedroom; private drinking thus commences, the habit is formed, and before the victim is well aware of the precipice which yawns before her, she has fallen from all that was lovely and refined in a British maiden, and becomes a candidate for admission to one of those asylums for female inebriates which shock the readers of newspaper advertisements.

The human frame is not one that can bear habitual disregard of its requirements, or habitual trifling with its complicated mechanism. There is a limit to its power of adapting itself to circumstances, which, when reached, everything begins to go wrong, and disease is the result. The chemico-vital operations momentarily taking place in the body require for their performance a perfect adjustment of function and structure, which brooks no interference with impunity. Each thought, each movement, implies a waste of the cell structure of the body; albuminous food is necessary to repair the breach caused by every bodily or mental development of force, while hydro-carbons, such as sugar, starch, and oil, supply material for the combustion which maintains animal heat. Oxygen must be received in due quantity at the lungs, and applied to further the changes which must take place in the debris of the structures before they can be cast out of the system. If the balance between waste and nutrition is equally kept up, and sufficient repose enjoyed to enable each part of the body in its diurnal revolution to recover itself after exertion; if exercise of the moral, social, intellectual, and religious faculties accords with the amount of ability, physical and mental, which each man possesses, then life ought to run on in an uninterrupted stream, and terminate painlessly after a peaceful old age. But the stormy life of adversity and toil, the vicious pursuit of sensational excitement, the accidents to which all are liable, and the unnatural customs of civilised man, interrupt the course of life, disturb the equilibrium of the system, and give rise to diseased conditions of mind and body.

Two great sources of vitality exist in every human being, generating voluntary and involuntary force, the one presiding over thought and action, the other over the more directly animal functions. It would seem that one of these may be developed at the expense of the other, so that with apparent physical force there may be low animal power.

It may be that the prodigious exertions in thought and deed of the men of this generation have developed their brains and voluntary muscles at the expense of those internal organs which support animal life, but, however that may be, certain it is that a condition of low vitality marks the generation, and becomes apparent when accident or disease have disturbed the harmonious co-operation of the various functions of life. It was not without reason that St. Paul wrote to the overworked Bishop of the early Church, "Use a little wine for thy stomach's sake, and thine often infirmities," for the labour of organising a new Church amid prejudice and persecution must have been most exhausting. But although this first recorded prescription of alcohol as a medicine proceeded from such a high, moral, and religious authority, there are well-intentioned men mistaken enough to carry their extreme teetotalism even to the bed of sickness.

Physiology and chemistry, aided by modern appliances for discovering and analyzing vital operations, have of late years explained many things which our ancestors considered mysterious, and have thus gradually affected a change in the practice of the healing art. Now, instead of blindly groping after specifics by which to cure disease, and thwart nature, the physician often has to recognize in the paroxysm of disease, an effort of the system to free itself from something which, generated within, or received from without, is opposed to its operations; he sees before him the vitality of the sufferer engaged in mortal conflict with a deadly foe, and instead of drawing away the life blood, and starving out the garrison, he throws in supplies through every available channel, and assists nature to expel her enemy in her own way. Food thus becomes the most important ally of the physician; but unfortunately the digestive organs generally share in the general depression of the system induced by disease, and cannot further those chemico-vital operations through which food has to pass before it can be changed into vital force.

It is under these circumstances that alcohol, which is *directly* absorbed by the veins of the stomach, and enters the circulation in a few moments, becomes all-powerful, and by a fourfold operation, conducts many a sick man past the very jaws of death to a renewal of life.

It is a question still under debate whether alcohol is food or not,[1] recent experiments would lead us to believe that it is so, although, even as a hydro-carbon, it is much inferior to sugar, starch, or oil; but its action in disease is quite independent of any such assumed power, for even if it be admitted that it adds no real force to the system, it undoubtedly calls latent force into action through its primary influence on the languishing nerves. Just as in one of those boat-races which attract the eager and interested spectators of manly feats, emulation, ambition, hope, and a ringing cheer for the university, without adding anything to the power of jib, freshman, or fellow commoner, stir up the latent energy, and put on the spurt which drives them in to victory, outdoing themselves as well as their competitors; just so alcohol spurs the vis-nervosa, and tides over the critical, and what without it would often prove the fatal day. But it does more than this, for it tends also to rouse the dormant power of digestion, secretion, and excretion, so that food may be again assimilated, and poisons expelled from the blood. Further, in most acute diseases, a rapid oxygenation is consuming the tissues, maintaining febrile heat, and burning off the supplies of life's garrison, this alcohol tends to check, for, in common with all hydro-carbons, it has a powerful affinity for oxygen, and by appropriating that element to itself, makes a diversion in favour of vitality, and economises existing supplies; this latter object is also effected through the secondary narcotic action of alcohol. Thus, as I said before, alcohol is a medicine of fourfold operation in disease, and expended as it is in accomplishing the purposes for which it is given, it does not intoxicate, and may be consumed with safety in much larger quantities than in health. Just as the boiler of a steam-engine is safe while the locomotive moves freely along the rails, and the mighty force within is expended in propelling the ponderous mass, but bursts if the machinery is arrested, unless the safety-valve permits it to escape; so when the system is below par, alcohol expends its force in raising it to par, and when too rapid oxygenation is consuming the tissues, the hydro-carbon, by diverting oxygen to itself, preserves the structures from excessive waste. But how different its effect in health, especially during youth, when the functions are habitually above par for purposes of growth and development, and when oxygen, the great purifier, is more especially required to perfect the ceaseless changes on which rapid motion depends! Then alcohol creates a morbid excitement which is followed by a corresponding depression; that depression necessitates a further supply of the stimulant—a hair of the biting dog—as the saying is, for its cure. This affords temporary relief, but at what a price! for still greater depression soon steals over the victim, and in time an instinctive craving for alcohol is established, as strong as hunger, as uncontrollable as thirst. A revolution has taken place in the nutrition of the body, and every microscopic cell of the millions which compose its tissues and organs thirsts for alcohol, instead of hungering for food.

PROFESSOR BAMBERGER ON ACUTE POISONING WITH PHOSPHORUS.

(Reported by C. Arbo.)

Translated from the *Norsk Magazin for Lægevidenskaben*, xxii. Bind., 3 Hefte, Christiania, 1868, by

W. D. MOORE, M.D.Dub. et Cantab., L.K.Q.C.P.I., M.R.I.A.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

(Continued from page 107.)

The anatomico-pathological phenomena were in general the same as have been observed and described by others. The animals experimented on were rabbits, whose stomachs are almost always filled with tolerably consistent ingesta. The mucous membrane of the stomach was often entirely intact, which, perhaps, depended partly on the fact that the granules of phosphorus, divided in the food, did not always come in contact with the wall of the stomach. Sometimes circumscribed hyperæmias and ecchymoses were met with; never ulcerations. The mucous membrane of the duodenum was usually also swollen; sometimes it was suffused with blood, but never ulcerated. The jaundice, which is so constantly observed in phosphorus poisoning, must therefore be regarded as gastro-duodenal (as which, moreover, Munk and Leyden considered it) if it should be shown that a similar affection of the duodenal mucous membrane occurs also in men after poisoning with phosphorus. A peculiar alteration of the cells in the pepsin-glands in the stomach, observed by Virchow, was seen by Bamberger only once in his animals. The rapid occurrence of fatty degeneration of some organs, which was often demonstrable even after two or three days, was always striking. The liver frequently consisted, as it were, of a single fatty mass, so that scarcely an hepatic cell was discoverable which did not contain drops of fat. The kidneys were also in a state of advanced fatty degeneration; they were large, of a yellowish appearance. The urinary canals in the cortical substance were quite filled with fat. The epithelium was, for the most part, in a state of degeneration, and was loaded with fat. The pyramids were less degenerated.

This degeneration gave Bamberger the idea of a passive process. He could scarcely look upon it as active. In the muscular structure of the heart the transverse striæ were indistinct, or entirely wanting. The fibrillæ were studded throughout with drops of fat. In almost all the organs hæmorrhages or petechiæ were met with. They were particularly numerous in the lower lobes of the lungs.

To demonstrate the presence of phosphorus in the blood, he took at different times blood from various parts of the vascular system, as from the carotid artery, the inferior vena cava, and the vena portæ. The first experiments were negative. It soon appeared, however, that this negative result depended on defects in the method of investigation; for, as phosphorus in the form of vapour is very volatile, it might be volatilized even in the preparatory manipulations. In the examination of the parenchymatous organs this must take place to a still higher degree, as, for the sake of investigation, they must be introduced into the vessel in small pieces, and must therefore in every case remain long in contact with the air, whereby evaporation and oxidation are favoured. To avoid this Bamberger introduced a small glass tube into the vessel from which the blood was to be taken, connected this with an Indian-rubber tube, into which, again, a bent glass tube was inserted; this last was conducted into a receiver containing a solution of sulphate of soda, to prevent the coagulation of the blood. In this mode the blood drawn scarcely came into contact with the atmosphere, and Bamberger then succeeded in demonstrating the presence of phosphorus in the blood from the vena cava, beyond the junction of the hepatic veins, which must therefore have passed unchanged through the capillary system of the liver. On the other hand, it was not possible, after the internal administration of phosphorus, to demonstrate its presence beyond the pulmonary circulation in the blood from the carotid, but if the phosphorus, dissolved in oil, was injected subcutaneously, it could be demonstrated in the blood from the carotid—a proof that it can pass, partly unchanged, even through the capillary system of the lungs.

From these experiments Bamberger came to the conclusion that *phosphorus volatilizes in the stomach, and that the vapour of phosphorus there formed comes by diffusion unchanged into the mass of the blood* (as the volatilization of phosphorus takes place with tolerable activity at the ordinary temperature, it must be decidedly favoured by the higher temperature of the stomach). *Once taken into the blood, it circulates with the latter, becomes gradually oxidized by its oxygen, but at the same time produces essential changes in the organs.*

This condition of the phosphorus in the system having been discovered, the question remains as to the fatty degeneration of the organs. This process is allied most closely to the acute yellow atrophy of the liver, though in phosphorus poisoning the fatty change is much more rapidly established. In this case a specific effect of phosphorus suggests itself, and we must distinguish between many possibilities. It is well-known that phosphorus dissolves in fats and oils; as the blood contains from one to three parts of fat in a thousand, it was conceivable that the phosphorus dissolved in this fat, was separated with it, and thus caused the fatty infiltration of the organs. Or it might be assumed that the albuminous bodies of the blood were, under the influence of the phosphorus, transformed into fat, as under some circumstances a metamorphosis of albumen into fat is observed; or, finally, the metamorphosis of the fat of the body might be hindered in one mode or another. In the first case the blood would become impoverished in fat; in the second and third cases an excess of fat must be met with. To discover the true state of the case Bamberger instituted some experiments upon rabbits.

In the first place the amount of fat in the blood was ascertained in two healthy rabbits, and in one it was found to be 2·656, in the other 1·041 per mille; thus there are considerable differences even in the healthy state, as Becquerel established in man also a variation from 1·0 to 3·3 in health.

Further, the amount of fat in the blood of a rabbit which had fasted for a long time was estimated, and found to be 2·087—this result is nearly the mean of the first two values. (This experiment was necessary, as the rabbits to which phosphorus is administered for several days do not take any nourishment).

Lastly, the fat was estimated in two rabbits, one of which had in four days got 40 mgrm. of phosphorus, in it 1·322 of fat was found; the other had in five days used 50 mgrm. of phosphorus, and the amount of fat in the blood was 0·891.

A diminution of the amount of fat was therefore demonstrable, but it does not appear to be so considerable as to be available for any definite theory; such a diminution might be explained, also, by other causes than the administration of phosphorus. In no case was there any increase of the amount of fat. *It may, therefore, be assumed, that the phosphorus taken up into the blood effects such a change in the latter, that it becomes quite unsuitable for the nutrition of the organs, and that therefore the several organs fall into a state of retrogressive fatty metamorphosis, an acute marasmus, or it may be assumed that phosphorus supplied to the several organs, produces a new formation of fat in them.* Bamberger, however, considered the first alternative to be the more likely.

If the mode of action of the phosphorus were once ascertained, it would seem to be important to discover a suitable mode of treatment.

If phosphorus in the state of vapour has passed into the blood in large quantity, we can scarcely expect anything from medical treatment; at the most, transfusion might be tried, just as it has been employed, with some advantage, in poisoning with carbonic oxide. If in any given case it be probable that phosphorus still exists in the stomach, vomiting ought in every instance to be produced, though emetics are often of little use, as the particles of phosphorus adhere rather firmly to the wall of the stomach, and this organ does not always contract completely. The treatment now employed, consisting in the administration of magnesia, is scarcely of any use; for magnesia can act only as an alkali against the products of the oxidation of the phosphorus, by neutralising them, but these are to be considered as not injurious to the stomach.

Duflos proposed another method, namely, to give oxidizing bodies, and he recommended liquor chlori with magnesia usta, it was intended thus to hasten the oxidation of the phosphorus, and that the products should combine with the magnesia. Some assert that they have seen favourable results from this plan, others say that death has been at least postponed by it; most observers saw no result from it. Practically, we can scarcely promise much from this method, as the preparations of chlorine decompose so rapidly. As phosphorus acts in the system in the form of vapour, it is an object to discover a remedy, capable of limiting or preventing its volatilization. Bamberger found that phosphorus, brought in small granules under water into contact with a solution of sulphate of copper, and heated to from 77° to 88·2° Fah. soon acquired a black colour, which gradually extended beneath, while the surface acquired a metallic lustre, until finally the whole cortical layer consisted of metallic copper. The pieces of phosphorus thus coppered no longer shine, have no smell of phosphorus, and when heated (even to 99·5° Fah.) give not the slightest trace of Scherer's reaction.

By this coppering the volatilization is therefore to a great extent limited. To this, it might certainly be objected, that the system is no retort, and it might be doubtful whether the sulphate of copper would act similarly in the stomach ; Bamberger believes, however, that its action would be the same whether the stomach were empty or full, its contents acid or alkaline. On the other hand, it will probably be rejected by vomiting, and to continue its use it must be given in a rather dilute state, or another salt of copper, which does not produce vomiting, must be employed. Such a salt is the carbonate, whose effect may be promoted by the addition of vinegar and a gradual change to acetate of copper. He would, therefore, propose the following treatment :—

First give sulphate of copper as an emetic, after repeated vomiting give it still in smaller doses, and if it be not borne, substitute the carbonate in doses of from five to eight grains suspended in water, drinking after it a teaspoonful of dilute vinegar. At first, this dose must be given every quarter or half-hour, afterwards at longer intervals. Between the doses let the patient take cold things, iced water, ice in small pieces, in order on the one hand to combat the symptoms of gastritis, on the other, by the lower temperature to diminish the volatilization of the phosphorus. After some hours, the emetic is repeated to remove the portions of phosphorus now covered with copper, which may still remain, and which no longer adhere so firmly to the wall of the stomach.

Bamberger had not as yet been able to institute satisfactory experiments, for the animals at his disposal were rabbits and dogs ; but the first have the stomach always filled with a quantity of food, and the latter usually vomit every foreign substance very rapidly, and neither, therefore, appear to be well suited for experiment. He has as yet had no opportunity of trying this treatment on the human subject ; should this treatment also prove to be defective, he believes, nevertheless, that with respect to it, the proverb may be applicable : "Inter cæcos monoculus rex."

Correspondence.

OXFORD MEETING OF BRITISH MEDICAL ASSOCIATION—ARRANGEMENTS FOR AN ANNUAL MUSEUM

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At the meeting of the British Medical Association, to be held in Oxford next week, an Exhibition Room will be set apart as a temporary Museum. It is proposed to collect in it any objects of professional interest recently obtained.

The following are especially contemplated :—1, Instruments and surgical appliances ; 2, Casts, models, photographs, drawings, &c., illustrating subjects in connection with medicine or surgery ; 3, New drugs, or pharmaceutical preparations ; 4, Pathological preparations ; 5, New books, especially those containing illustrations ; 6, Models, &c., of inventions relating to hygiene, &c.

As far as may be, objects exhibited ought to be new within the last twelve months, but this limit need not be rigidly observed.

All objects intended for exhibition should be consigned to the care of Dr. Gray, the University Museum, Oxford. The authorities of the museum have kindly set apart a commodious room for the purpose.

The Annual Museum will open on Tuesday morning and remain open till Friday evening. Objects for exhibtion should be removed on Saturday the 7th.

Exhibitors must defray all the expenses of packing, carriage, &c. No object can be displayed unless accompanied by a concise description.—I am, dear sir, yours truly,

JONATHAN HUTCHINSON,
Hon. Sec. in London for the Museum.

4, Finsbury Circus, E.C., July 29, 1868.

UNDERPAID POOR-LAW MEDICAL OFFICERS IN ENGLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Many thanks for your notice of my case ; the Poor-law Medical Officers in England are under a debt of gratitude to you for "hitting the right nail on the head." My friend, Dr. Paton, who was staff-surgeon of the Turkish Contingent, afterwards held an appointment as Medical Officer in the Morpeth Union ; well, he threw it up for an increase of salary, it was only £5. The Guardians advertised in vain, no one would take it at that sum. They raised it to £10, but no sooner was this done, than the Doctor found "There was another Richmond in the field," and more provoked than ever to find a brother practitioner ready to oust him for this paltry increase, he, very unwilling, solicited and obtained the appointment. On his succeeding to the appointment of surgeon to the workhouse, he again threw it up. By this time his former rival had "vanquished left the field," and although a newly fledged, single, qualified man had spread his pinions, he would not accept the duties for £10, so the Guardians quietly offered him £15, which he accepted. Now, sir, I say you are right, and if it was not for the perfidy and treachery of our own brethren, we would soon be recompensed according to our work. "It is true, and pity 'tis, 'tis true," that men will in a public capacity (such as Guardians) *do and say things* that as private individuals they would be ashamed of.—I am, yours, &c.,

J. C. REID, M.D.

UREA AND URIC ACID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I have long been of opinion that uric acid in the human system is the immediate result of a deficient supply of oxygen in the blood, and consequently, that the only rational treatment for removing it consists in such processes as favour its elimination, combined with an increased supply of oxygen to the blood, and a diminution of the supply of nitrogen, which principally enters the system in the form of animal food.

I will not now, however, enter into the best means of favouring the elimination of uric acid, as my principal object is to show that it arises from a *deficient* supply of *oxygen*, or *excess* of *nitrogen* in the body, and will accordingly be found most frequently to afflict the carnivorous, and those leading a sedentary existence. Now for the proof—$C_{10}\ H_4\ N_4\ O_6$ are the chemical equivalents of uric acid, if 4 atoms of water $= 4\ H, O$, be added, we have $C_{10}\ H_8\ N_4\ O_{10} = C_4\ H_8\ N_4\ O_4 + 6\,(co) = 2$ atoms of urea $(C_2\ H_4\ N_2\ O_2) + 6\,(co)$; if to this product be added 6 atoms of oxygen $= C, O$, we have 2 atoms of urea $+$ 6 carbonic acid $6\,(C\ O_2) = 1$ atom of uric acid $+$ 4 atoms of water $+$ 6 atoms of oxygen ; thus showing that 6 atoms of oxygen, in addition to 1 atom of uric acid, are required to form 2 atoms of the soluble substance, urea, and to oxydate thoroughly the accompanying 6 atoms of carbon. Hoping this formula, which I am not aware has ever been presented to the profession before, may reconvert Dr. Kelly to his former sound opinion, and influence medical treatment accordingly, I remain, your obedient servant,

RICHARD GRIFFITH, jun., Ch. M.

Cork, July 23rd, 1868.

THE TREATMENT OF ACUTE RHEUMATISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I think many of your readers are not aware of the extraordinary efficacy of valerian, adminstered in the form of a bath, in subduing the pain and inflammation attending acute rheumatism, particularly of the arthritic form, and consider I am merely fulfilling a duty to the profession and public by mentioning it. It was first introduced to my notice by my friend, Dr. Adrien—a name known and honoured in the annals of Dublin surgery—since which time I had opportunities of testing and proving its wonderful power of arresting and cutting short the most violent attacks of acute rheumatic arthritis. The bath is made simply by taking lb. i. of valerian root, boiling it gently for about a quarter of an hour in one gallon of water. Straining and adding the strained liquid to about twenty gallons of water in an ordinary bath. The temp. should be about 98°, and the time of immersion from twenty minutes to half an hour. Pains must be taken to dry the patient perfectly upon getting out of the bath. If the inflammation remain refractory in any of the joints, linseed meal poultices should be made with a strong decoction of valerian root, and applied.—I am, sir, yours, &c.,

N. J. BUTLER, L.C.P.L., &c.

SICK CLUBS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your remarks (in your article "Sent to Coventry") upon sick-clubs, in your issue of July 15th, reminds me that there are many sick-clubs in Dublin, and some especially which, if report speaks truly (which I do not positively assert it does) require even more revision as to tariff than those referred to in your article.

I should like to know who are the medical officers? What is the subscription? and what are the salaries of the members of certain sick clubs, which I understand exist in connection with rank in this city? I should also like to be informed if it be true, that Civil Service Clubs, with salaries of £500 and £600 a-year obtain medical advice for a subscription of £1 per head per annum to the Civil Service Medical Attendance Association?—Yours obediently,

AN HOSPITAL PHYSICIAN.

Dublin, July 1868.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows, held last Thursday, July 30th, the following gentlemen, having undergone the necessary examination, were duly admitted members of the College:—David Anderson Moxey, M.D., Edin., Edinburgh House, Turnham-green; Joseph Frank Payne, M.B., Oxon., St. Mary's Hospital, Paddington; John Jones Phillips, M.D., Lond., Guy's Hospital; Thomas Pigg, M.D., St. Andrews, Manchester; Joseph Rutter, M.D., Lond., Brighton; Robert Temple Wright, M.D., Edin., 10, New Ormond-street.

EDINBURGH PHILOSOPHICAL INSTITUTION.—On Wednesday evening a meeting of the members of this Institution was held for the purpose of electing a successor to the late Lord Brougham as president. Mr. William Smith, vice-president (who occupied the chair), moved that Mr. Thomas Carlyle be elected. Professor Masson seconded the motion, which was unanimously agreed to. The Chairman then stated that it afforded him sincere gratification to announce, on the part of Mr. Carlyle, his acceptance of the office, and to convey the thanks of that gentleman for the honour the meeting had conferred upon him.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—A Meeting of the Central Committee of the above Society was held on 28th ultimo. Mr. Tufnell in the chair. The secretary read an application for relief from the widow of a medical man recently deceased. The husband died from pyemia, subsequent to a fracture of the neck of the thigh-bone, which he received by a fall from his car, when proceeding at night to a patient. He was a comparatively young man, and had been unable to lay by anything or insure his life; he leaves a widow and 12 children totally unprovided for. This case was strongly recommended by the Local Branch for the largest grant that could be given, but the hon. treasurer stated that there was only £2 in hands. The committee should therefore have been obliged to refuse a grant, were it not for the liberality of one of the members, who advanced £15 till funds were available. The treasurer was instructed to send this sum to the local secretary, and a vote of thanks was passed to the member who so handsomely and generously came forward in this emergency.

THE BRITISH ASSOCIATION.—At a meeting of the representatives of the various public bodies and learned and scientific societies in Edinburgh, held on Thursday, the Lord Provost presiding, a committee was appointed to take the requisite steps for inviting the British Association to meet in that city in 1869. Sir George Harvey, Professor Christison, Professor Balfour, Professor Spence, Professor Duns, Sheriff Maitland Heriot, and others took part in the proceedings.

DIPSOMANIACS.—The Lunacy Board for Scotland in a former year's report expressed an opinion that persons unable to resist the the tendency to excessive drinking should be allowed to place themselves under control and treatment without authority from the sheriff. The Board have now to state that, by the Lunacy Amendment Act, 1866, asylums are anthorized to receive for care and treatment any person who expresses in writing to the Commissioners in Lunacy his wish to become a voluntary patient, and obtains their consent, and that this provision was taken advantage of in 1867 in Scotland by 17 persons; 14 were admitted into public and three into private asylums. These patients, however, were not necessarily all dipsomaniacs.

AT a recent meeting of some of the gentlemen interested in a charity called the "Jewish Blind" a remarkable case was brought under the notice of president, Sir Benjamin Phillips. A woman (stone blind) has been in receipt of a pension for about eight years. During a heavy storm that prevailed some weeks since, she became suddenly aware, as she expressed it, of "a glimmer of light," and from that time to the present her vision has improved daily; perfect eyesight is now restored to her. The poor woman expresses herself as having been "greatly shocked" at the thunder and lightning.

STATISTICS OF INSANITY IN SCOTLAND.—The Board of Lunacy for Scotland state in their tenth report, which has been laid before Parliament, that the mortality in Scotch asylums compares favourably with that in English and French establishments. In the five years 1862-66 the annual rate of mortality on the average numbers resident in Scotch asylums was 8·24 per cent.; in English asylums, 10·39 per cent.; in French (1854-66), 14·03 per cent. In all three countries the male mortality was greater than the female; but the excess was less in Scotland than in England and France. The proportion of recoveries from insanity is also considerably more favourable among females than among males. According to a table issued by the Scotch Board showing the admissions into Scotch asylums from 1858 to 1867, it appears that of every thousand patients who recovered in the 10 years, 431 were males and 569 females. In 1867 the proportion of female pauper lunatics to every 100 male pauper lunatics was 116. The returns, however, do not supply means of making a safe deduction of the relative tendency of the sexes to insanity. The proportion of the whole number of pauper lunatics to population in Scotland on the 1st of January, 1866, was 1·826 per 1000; the average of the preceding seven years 1·742 per 1000. The proportion varied greatly in different counties. As a rule, it may be assumed that there is a greater degree of mental activity among an urban and manufacturing population than among an agricultural, and to this fact may possibly be ascribed the more frequent occurrence of insanity among the former. But it must be taken into account that the increase of lunacy is found chiefly among the lower classes, who do not display much mental activity anywhere, but who are more exposed in urban and manufacturing communities to overcrowding and impure air, exhausting labour, insufficient diet, abuse of stimulants, and contagious diseases. Over-excitement of the intellect or feelings is doubtless a not infrequent cause of insanity; but among pauper lunatics in asylums the cases which originate in this source are few in comparison with those which are due to physical deterioration. The total number of insane persons in Scotland, of whom the Board of Lunacy had official cognizance on the 1st of January, 1867, was 6762; 5594 supported by parochial rates, 1168 by private funds; 3178 males, 3584 females. There were also 45 criminal lunatics in Perth prison, making 6807; and there was a considerable number of cases not known to the Board, maintained in private dwellings from private resources. The admissions into public establishments in 1867 comprised 805 males and 900 females; the recoveries were 303 males and 401 females. In the ten years 1858-67 the admissions were 6199 males and 6996 females; the recoveries, 2455 males and 3242 females; the deaths, 1927 males and 1761 females.

A considerable number of distinguished literary and scientific men of New York have recently met for the purpose of discussing the advisability of founding an American Academy on the model of the French Institute.

Lecture.

THE USE AND ABUSE OF "STIMULANTS."

By W. JACKSON CUMMINS, M.D.,

PHYSICIAN TO THE CORK SOUTH INFIRMARY AND COUNTY GENERAL HOSPITAL, EX-PRESIDENT CORK MEDICAL SOCIETY, ETC.

(A Lecture delivered before the "Cork Young Men's Association," January 7th, 1868.)

(Continued from page 131.)

Man in his natural state has voluntary power, a will which makes him master of his own acts, being only in subjection to those instinctive desires which are necessary to the preservation of life; but when the laws of nutrition are set aside by the habitual use of alcohol, and natural appetite has given place to the greed for strong drink, he becomes bondslave to a hard taskmaster, which robs him of volition, intellect, morality, health of body, and peace of mind, and becomes "like a weed."

> "Flung from the rock, on ocean's foam to sail,
> Where'er the surge may sweep, the tempests' breath prevail."

I have seen delirium cease under the influence of intoxicating doses of wine and brandy during fever, and I have seen, in the same person, much smaller quantities produce the delirium of intoxication after the crisis had been passed through. While the fever was present the alcohol never accumulated in the blood as alcohol, being rapidly decomposed by the union of its carbon with oxygen to form carbonic acid, and of its hydrogen with another part of oxygen to form water. As I have already told you, this union with oxygen is beneficial when feverish combustion of the tissues by that element is taking place; but the very opposite is the case in health, when oxygen, which is received into the blood at the lungs is the chief source of its depuration.

It is so necessary, that if its entrance is completely shut off, as in drowning or suffocation, carbon, a deadly poison, generated within the body, accumulates with such rapidity that life becomes extinct in a few minutes. Now, it is quite obvious that where the quantity of oxygen which can be inhaled is limited, and where a plentiful supply is required for the removal of the debris of the tissues, any agent which appropriates oxygen to itself must cause death slowly in the same way that suffocation does quickly, by depriving the body of oxygen, and thus allowing hydrocarbonaceous poisons to accumulate in the system. Those who are given to the gentle sport of trout-fishing, anathematise the little country boys who throw lime into the mountain streams in summer, in order to catch the suffocating fishes, as they float upon the surface of the water; but it is not generally understood that the young poachers are only doing for the trout what the dram-drinker does for himself, by putting in a substance which, having an affinity for oxygen, deprives the water in one case, and the blood in the other, of what is as necessary to the existence of fishes as of men.

When we consider this simple truth, we cannot be surprised that the system has a remarkable intolerance of alcohol, and endeavours to cast it out as quickly as possible, so that unless the dose is so frequently repeated that one overtakes another in the blood, accumulation cannot take place, and evil does not result. But the habitual use of alcohol in any form first overtaxes the organs through which it is removed, and when they fail, a gradual accumulation, not only of the poison itself, but also of the unoxidised impurities generated within takes place, and in time the body becomes a very charnel-house of corruption, a body of death chained within the body of life.

One of the latest and best authorities of the day[1] enumerates no less than twenty-six diseased conditions of mind and body directly due to alcohol, and I told you before that it is said that 60,000 lives are annually lost in Great Britain through its direct or indirect effects. This is fearful to contemplate, even in a social point of view, but how appalling when we consider the value of each immortal soul which thus rushes with suicidal precipitancy into the presence of its Maker! Truly; we cannot help exclaimin with Shakespeare—"Oh, thou invisible spirit of wine, if thou hast no name to be known by, let us call thee devil!"

Time does not permit me to enter more fully into the positive ill effects of the abuse of alcohol, and with a few words I must pass over its negative evils. Each of us is accountable to our Creator for every thought and act, and every talent committed to our care ought to gain another talent, besides, if we would please Him who has called us to be His stewards. Surely every one who has indulged in more than a very moderate quantity of alcohol must feel and know that he has unfitted himself for the performance of his duty to God and to his neighbour, as a condition far short of intoxication diminishes both moral and physical self-control, as well as the full power of body and mind.[2]

---

[1] Aitkin's "Practice of Medicine."

[2] Parker "On Hygiene."

One of the ablest physiologists and physicians of the day says that, "If we look upon the body as an agent of work, from which we desire to obtain as much mechanical and mental force as is compatible with health, we must consider the effect of alcohol as simply a means of preventing the development of force." Now, as responsible beings, I maintain that we have no right to trifle with our bodily or mental powers, and that we are accountable for the full measure of usefulness that can be derived from them.

But it may be objected, to this, that instances have occurred of individuals whose talents never show out in full brilliancy except when they were well primed with alchol! such exceptions, however, only prove the rule as laid down by physiologists; and we may well ask ourselves the question—when we ponder over the history of great men, who had so far become the victims of self-induced disease, as to require the spur of semi-intoxication to enable them to pour out the riches of their genius—we may ask ourselves, I say, what such men would have been, and how much greater benefit their less gifted fellow-creatures would have derived from their talents; had they not bartered the best part of their lives, and full control over their super-human faculties for the indulgence of an hour.

An idea that alchol in moderation is useful as a support under prolonged exertion, or exposure to extremes of temperature is very generally entertained, and nothing can be more opposed to fact, as testified by those observers who have had the best opportunities of judging. Many trainers for athletic sports absolutely forbid wine or spirits, and those who allow them do so only at meal time, and in very great moderation; from this we would conclude that practical experience has demonstrated to a class of men whose prejudices would rather lead them to favour alcohol, that it impedes the developement of force. Let a sportsman test for himself a hard day's fagging with water as a beverage, and another with alcohol in moderation, and he will assuredly find that his enjoyment has been keener, his aim truer, and that he returns home less weary,-albeit with a heavier bag, when he has left the brandy-flask at home.

I once made a voyage in an American temperance ship, and was greatly struck by the superior seamanship and steadiness of the crew, as contrasted with the same class in ships where I had seen grog regularly served out.[1] In the late American war it was optional with the colonels of Federal regiments either to serve out or forbid stimulants to their men, and we are told that the difference between the abstinent and temperate regiments, as to courage, discipline, cheerfulness, and power, was most remarkable.

Although alcohol is a hydrocarbon,[2] its heat producing power is inferior to fat, in the proportion of 1 to 2 two-third, and all experience goes to prove that in the Artic Regions animal heat can be much better sustained without it; so well-known is this,[3] that the Hudson Bay Company has for many years entirely excluded spirits from the fur countries over which it has control,[4] and among the 700 or more American ships engaged in the whale fishery, the abstinence principle has been almost universally adopted from a general conviction of its practical superiority.

Sir John Richardson,[5] the companion of Franklin in his first Artic expedition, Dr. Kane, Mr. King, Captain Kennedy, Mr. Goodsir, and other high Artic authorities, all speak favourably of the abstinence system, so that there can be little doubt that alcohol fails to protect the system against extreme cold.

If we turn to the tropics we find, as we should expect, decided testimony of the injurious effect of alcohol even in moderation, under exposure to the influences of the climate. To use the words of Carpenter—"the advantage of total abstinence over moderation is evidenced by the experience of our Indian army, as the Government returns of the three classes, of teetotalers, temperate, and intemperate, authoritively proves." . . . "The mortality of the intemperate was nearly double that of the temperate, while that of the moderate men was more than double that of the total abstainers."

This testimony is sufficient in itself to establish the fact that neither brandy and water, nor beer, which are so much partaken of in India, are necessary for the support of the system under the relaxing heat of the tropics.

Figures also goes to prove that even the moderate use of alcohol is injurious in a temperate climate such as our own, for to quote from Professor Millar, "there is a life assurance office, last year, issusing upwards of 2500 policies, which has two branches, one solely for abstinants, the other for the ordinary business, the insured in the latter being of course a fair average of the 'temperate' men. These two branches, abstinent and temperate, have been in parallel operation for about seven years, and the result is 19 per cent. in favour of the abstainer."[1]

Figures drawn from the reports of abstinent and temperate sick clubs in Preston, show also a remarkable contrast in favour of the former.

I must apologise for quoting so many figures in a lecture of this kind, but really the information they convey on an all-important subject cannot take too prominent a place in a lecture addressed to "young men," proving practically as they do, what physiology and experiment would lead us to expect, that the habitual use of alcohol even in moderate quantities is prejudicial.

I confess, I cannot think, with many, that a glass or two of the "wine which gladdeneth the heart of man," may not, even in health, take its place in our social reunions, and be safely indulged in moderately, now and then, by those who have no tendency to take too much or to contract a regular habit, provided, also, they do not inherit constitutions prone to dipsomania or drunkenness; for these latter, the smallest potation is unsafe, and I may add that healthy children should never be allowed to taste wine until their growth and developement are complete.[2] In intemperate persons the mortality from 21 to 30 years of age is five times that of the temperate; from 30 to 40 it is four times as great, and becomes gradually less as old age advances; apply this law from 20 years back to childhood, and you will see the extreme danger of stimulants to those of tender years. But to return, I cannot help thinking also that, taking men as we find them, it is not always possible to seperate between the healthy and those who have inherited or acquired a more or less diseased condition of body, which may be benefitted by moderate quantities of alcohol, especially at meal times, and that useful lives can be thereby preserved. After severe or prolonged exertion, too, when the energies of the system have been too long diverted from the organs of digestion towards the brain or voluntary muscles, and appetite has been thereby lost for a time, a moderate allowance of wine helps the digestive organs to recover themselves, and also promote subsequent repose.

Alcohol, as many are aware, retards digestion by coagulating the albumen of the food, if taken in a concentrated form, or in quantity beyond what is likely to be absolved rapidly by the veins of the stomach; but within certain limits, it tends only to stimulate the gastric secretions, and improve the tone of the stomach. It is unnecessary for me to enter into the many forms of indigestion caused by the directly irritant effect of alcohol in concentration on the delicate mucous membrane of the stomach; you can demonstrate it for yourselves, more satisfactorily than could the most eloquent words, by putting a drop of alcohol into your eye—an organ covered by a membrane similar to that of the stomach—and you can judge by the pain and irritation which ensue, what the poor stomach of the dram-drinker has to endure.

But there is in the system a power of casting out alcohol, when partaken of moderately, in a diluted form, occasionally, and thus preserving itself from injury. It is perhaps unfortunate, however, that there is also a power of tolerance, through which the system learns to endure the immediate effects of the poison when habitually imbibed, and to connive at those silent inroads which in time consummate the destruction of the most healthy body. It is against this treacherous effect of alcohol that we require most to guard ourselves, as it permits the formation of habit; habit, it is said, is second nature, but in this case it is even stronger than nature. It often, no doubt, springs out of the drinking customs of our country, which lure many a man into intemperance, and if there were any hope that the principles inculcated by total abstenance societies could succeed in rooting out drinking customs, I would advocate them with all my feeble power. In the back States of America, among an unexhausted and well-nourished population, free and independent, with a virgin soil before them as they spread themselves towards the far west, they may succeed, and I believe have succeeded, but in the eastern over-populated States of the same great Federation, drinking customs are as rife as in our own land. I have never seen more drinking anywhere than in New York—"sherry cobblers," "mint julips," "gin smashers," "eye opener," "fog dispeller," "bottled lightening," "moral 'suasion," "brandy coctail," "smasher," "illuminator," and other Yankee terms for strong drink, tell their own tale of American national intemperance. There, as here, drinking customs take root in social conditions closely connected with the Anglo-Saxon character and institutions, and I cannot help thinking that "teetotal" principles only create a minor evil, without any fair probability of removing the greater.

[1] Nepbalism, by Professor Millar
[2] Neilson's Vital Statistics, quoted in Parke's on Hygine.

"Teetotalism" has been tried under the most favourable auspioes in this country, and has lamentably failed; commenced by a clergyman of our own Church, the Rev. Nicholas Dunscombe, and carried into every cabin of our Roman Catholic poor by the great apostle of temperance, the mild and benevolent Father Matthew, it ought to have succeeded, if it could succeed, but the circumstances and conditions of the people were against it, and, although the enthusiasm and love of novelty of the Celt blazed up in temperance bands and processions and other excitments which, for a time, substituted the master passion, the amount of real good effected was only sufficient to make the gloom which has followed deeper than before.

The statue of Father Matthew stands in one of our principal thoroughfares, and beside it, on either side, a brilliant palace of alcohol, 500[1] public-houses in other parts of this chief city of his labours, also mock his memory, and defy only too successfully the principles which he spent his life in inculcating. In other parts of the United Kingdom the well-intentioned advocates of teetotalism have been equally unsuccessful, no less than 168,000[2] establishments for the sale of intoxicating liquors, in which 83 million of the capital of the country are annually spent, testifying to the practical inutility of the means by which they seek to crush out the great evil of alcoholic abuse.

If the causes of this blot upon our nation are such as I have endeavoured to point out, we cannot wonder that "teetotalism" has thus failed to keep it in check, and we turn with more hope towards the progress of social science, as a means of mitigating, if not eradicating, the evil.

The first and most important aim of philanthropists who are anxious to overthrow drinking customs ought to be to raise the religious, moral, and social character of the people, and endeavour to impart to all classes some practical knowledge of the physiology of common life, and the means by which a healthy condition of mind and body are best maintained: moderation in business and pleasure should next be inculcated by precept and example, and heavy penalties should be imposed upon those who overwork children, and deny them the physical and mental training which are essential to the proper development of their bodies and minds.[1]

Public baths and wash-houses should stand in every thoroughfare, and both cold and hot water should be liberally supplied, in order, if possible, to entice the lower orders into habits of cleanliness.

The Turkish bath, as a substitute for strong drink, is not at all as well-known or appreciated as it should be. Its effect is to carry out of the system those impurities which bad air, bad water, and bad food introduce into it, and it is a substitute for the exercise which many of the inhabitants of large towns have neither time nor energy to enjoy. It is, besides, a gentle stimulant to the nervous system, which leaves behind a grateful sense of elasticity and buoyancy, without loss of self-control.

Among the ancient Romans, the bath was used as a place of resort and social intercourse, and is so to this day among the Turks.

Happy would it be for the people of these countries if such an institution were to take the place of half the public-houses—if the Saxon and the Celt could laugh and sing, and crack their jokes, and smoke their pipes, over a cup of coffee in the cooling-room of a bath, instead of the reeking atmosphere of the public-house. Surely, the contrast would bring conviction to the senses, if not to the understanding of the best boon companion, and the great greed for whiskey and porter which costs so much money and so many lives, which wastes *so much time*, and causes such untold misery, would gradually subside, while contentment, if it could become the portion of an Irishman, would be more probably found in such an institution than in a public-house.

Sanitary science, as yet only in its infancy, has already improved the condition of towns, and amended to a slight extent the dwellings of the lower orders, and public feeling is so alive to the all-importance of a further move in this direction that we may look forward to a gradual uprising of the cloud of atmospheric impurities which hangs over our own cities, blighting and destroying the energies of the people, and leading to exhaustion and intemperance.

Much has been done in this city in the cause of temperance by the "Refreshment Rooms Company," which has placed wholesome, well-cooked nutriment within reach of the labouring class. We are indebted to the same company for cheap excursions down our beautiful river, and into the fresh pure air of the country, enabling husbands, wives, and children to seek pleasure in each others company, and to escape sometimes from the enervating atmosphere of crowded houses and narrow streets. They have also more lately organized cheap musical promenades in the Athenæum, which in time may be looked forward to by the working man with even greater pleasure than he now regards the Saturday night's debauch in a public house. Penny readings have also been commenced in our city, and cannot fail to elevate the tastes and feelings of the people, and to occupy the hours of recreation which many are prone to waste in dissipation.

After all I have said of over-work and exhaustion as sources of the use and abuse of stimulants, it may now seem strange that I should speak of idleness as producing a similar effect, but so it does, confirming the proverb, extremes meet. As a working man once said to me, "an idle brain is the devil's workshop." Over-exertion, as I have said, causes exhaustion, and thus leads to intemperance. Exercise strengthens the bodily powers and the mental faculties, but idleness produces lassitude and indolence, and these lead to every bad habit, and among the rest to intemperance.

---

[1] The author is indebted for these figures to Henry Humphries, Esq., Clerk of the Cork Police Court.

[2] Review of General Dow's speech in "Blackwood," Aug., 1867.

[1] Since this lecture was delivered, an Act of Parliament, passed last year (1867), has been made public, entitled the "Workshop Regulation Act." Cap. 146 regulates the hours of labour for children, young persons, and women employed in workshops. No child under eight years of age is to be employed in any handicraft; no child is to be employed on any one day for a period of more than six hours and a half, . . . not at all on Sunday, or after two o'clock on Saturday, with some exceptions. . . . No child under eleven is to be employed in grinding in the metal trades, or in fustian cutting. . . . A sum may be paid for schooling and deducted from wages, &c., &c. This is so far satisfactory, but it will be long before the present rising generation recovers from past overwork.

If a man has a happy fireside, and a well-regulated family, there ought to be pleasure enough in his home to keep him from the public-house; but young people, whose vital energies are in exuberance, require something more of active movement, and rational excitement, and society, to keep them from those gross and sensual pleasures into which the very love of doing something too often leads them. As the Rev. Dr. Guthrie says,[1] "public amusements, and social enjoyments are too little encouraged among us," and I have no doubt that one of the best safeguards for young men, when setting out into the world, is a love of rational society, especially among the ladies; as the saying is, they must "sow their wild oats," and far better is it for them to sow them in society which tends to refine and soften, and which demands at least an outward show of steadiness and sobriety on the part of those admitted within its pale, than in suppers and drinking, and gambling, and other debasing pursuits. But there is a vast difference between the rational and refining enjoyments I now allude to, and the idolatrous pursuit of sensual gratification and sensation from which the votaries of fashion seek in vain for pleasure and happiness; for, as I have already said, if we recklessly squander our vitality and vigour in the over pursuit of either business or pleasure, we must give them the spur of alcohol, and thus put an arrow into the quiver of death. Most carefully must we avoid indulging in pleasure to such an extent as to create a morbid craving for excitement; for the connection between moral and physical excitants is very close, and if once one of the better classes acquire a habit of "tippling," his downward progress is even more rapid than that of the poor man, who finds in his empty purse a compulsory term of sobriety from time to time. The costermonger comforted his "Sal." when she had spent her all on the Christmas treats, and sat biting her nails because she could get no more to drink, with the philosophic remark, "drunk on Sunday, on Monday, on Tuesday, arn't you satisfied, do ye want to be a hangel entirely." But the rich man lacks the poor man's safeguard, and can be a "hangel entirely," hence his danger, and herein the necessity for some restraint being imposed upon his too easily gratified propensity.

The question of reformation for drunkards has attracted much attention of late years, and asylums for inebriates have sprung up in many places; but the legal power to control the dipsomaniac is as yet wanting, and the good which might be affected by such institutions is thereby limited.

If the law treated inveterate drunkards as insane persons, which in truth they are, and permitted their friends to confine them in asylums on the certificates of two, or more, medical men, counter-signed by magistrates, clergymen, &c., forbidding their discharge except on tickets-of-leave, which could be recalled if the old habits were resumed; many of those useless members of society, who destroy themselves and their families, and disgrace their friends, might be rescued from the destruction of soul and body to which their propensity, sooner or later, consigns them. I regret that time does not permit me to enter more fully into this important branch of my subject, and I have pleasure in referring you for further information to a[2] valuable and suggestive essay by an accomplished physician who was once a townsman of ours, Dr. Belcher, of Dublin.

I have only one more suggestion to add to this brief and imperfect sketch of the means by which our national intemperance may be mitigated; it is the duty of every one who has opportunities of studying the physiological effects of alcohol, to spread abroad that knowledge to the fullest extent of his ability. Men are rushing blindly to destruction, and we have it in our power to open their eyes. It is only human nature to disbelieve moral treatises and sermons, and such like, when they war with our inclinations, but if we can succeed in *opening the eyes* of a man's understanding, and *showing* him the peril towards which he is running, we enlist on our side the principle of self-preservation, which is also a part of human nature.

The medical profession incurs some responsibility in recommending alcohol as a medicine, but the writings of such men as Carpenter, Parkes, Millar, and others, *who are accepted* as *standard authorities*, redeem the entire faculty as a body, from the charge of originating drinking habits. Every *individual* who has the honour of practising the noble science of medicine, ought as cautiously to guard his prescription from abuse, and as carefully protect himself from the reproach of having led a fellow-creature into excess.

Young men! I have come before you as a physician, and have accepted all the responsibility of a position which carries with it considerable influence upon the welfare of our common humanity. I have endeavoured conscientiously to perform the duty I have undertaken, but before we separate, I must address a word to any young man, if such be present, who has been unfortunate enough to contract a *habit* of using or abusing stimulants. Let me entreat you to pause ere you go one step further along the "broad road that leadeth to destruction;" even if abuse has been carried far, it is still quite safe, in the immense majority of instances, to give up the stimulant at once and for ever; and if your physician considers it safe for you to do so, use only sufficient, religious, and moral self-control, and you will succeed. The combat between duty and inclination is tough enough at first, and requires no ordinary resolution, but in time, habit will be found in the new direction, and then the path of duty will become not only the path of safety, but the path of pleasure also. There are rare cases where long continued habits of intemperance have so altered the nutrition of the nervous system, that a sudden change to sobriety would result in insanity or delirium tremens. Happily, the cases of the former, *directly* due to this cause, are infrequent, and the latter is much more frequently caused by persistance in the abuse of alcohol, than by giving it up suddenly. But it must be admitted that there are rare cases—and sad spectacles they present—of remorseful men striving might and main in a spirit of self-denial and endurance to shake off the chains of alcohol, and yet driven back to it again and again, as the only means of escaping from the spectral illusions of a demon-haunted imagination.

These diseased conditions demand the anxious and careful moral and physical treatment of the physician, and they illustrate in the most forcible manner the danger of contracting a habit which may become incurable; and yet they need not deter the unhappy slave of alcohol from making an effort to escape from bondage, for he may rest satisfied that he will almost succeed if he sets about it in *the right way*.

Hitherto I have spoken to you as a physician and physiologist, but I am sure you will not think I transgress the legitimate province of a lay lecturer if in conclusion I point out what is "the right way."

The Word of God says, "There hath no temptation taken you but such as is common to man, and God is faithful, who will not suffer you to be tempted above what ye are able to bear, but will, with the temptation, make a way for you to escape."

It is on his bended knees that the slave of alcohol can *alone* find the "way to esacpe,"—distrusting himself and his own resolutions—let him come to Him who says, "My grace is sufficient for thee," and who "giveth us the victory through our Lord Jesus Christ."

ANTIDOTE FOR STRYCHNIA.—Dr. J. Bartlett strongly recommends common salt as a curative of strychnia poisoning. He reports as many as twenty experiments on dogs, in which violent symptoms following large doses of strychnia ceased after emesis, induced after drenching the animal with water holding in solution several handfuls of salt.—*Chicago Med. Times.*

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

Cases of Luxation under the care of Mr. CROLY.

Case 1.—Luxation of lower jaw (double).

J. M., aged 20 years, a housemaid, living in the vicinity of the hospital, worked very hard, and went to bed late and tired. She yawned frequently, and then experienced a painful sensation in front of each ear, and could neither speak nor close her mouth. She came to the hospital, and presented the following appearance:—Her mouth was widely open, and her chin projected. She could not speak distinctly. There was a well-marked depression in front of each ear, and a prominent tumour under the zygoma of either side.

Case 2.—Luxation of lower jaw (single).

Mrs. L., aged 70 years, presented herself amongst the extern patients with well-marked luxation of the *left* side of the lower jaw, produced some hours previously by yawning.

Her chin was twisted to the *right* side, and the condyle of the jaw could be easily felt beneath the zygoma. There was a depression in front of the ear. The patient could not articulate, and appeared to suffer a good deal of distress.

Mr. Croly performed reduction in these cases in the following manner:—The patient was seated in a chair, and the head held steadily against the breast of an assistant. The thumbs (only one being used in case 2) guarded by a few folds of a handkerchief, were placed in the mouth on the base of the coronoid process, and the jaw depressed. The condyles were immediately restored to their normal position by the action of the muscles. A piece of cork, of wedge-shape, and grooved for the teeth, was placed at each side between the jaws, and a four-tailed bandage applied to the head.

Remarks.—Luxation of the lower jaw usually occurs from yawning, and is easily recognised. Reduction was effected in these two cases by Nélaton's method—viz., by merely dislodging the condyles of the lower maxilla from their abnormal position, muscular action completing the reduction.

Case 2 is remarkable, having occurred in a woman advanced in years, which is an unusual occurrence.

In neither case was there a flow of saliva, nor a sudden snap on the reduction being effected, as mentioned by surgical writers.

DR. STEEVENS' HOSPITAL.

Under the care of Mr. COLLES.

(Reported by R. L. Swan, Resident-Surgeon.)

EXOPHTHALMIA: RECOVERY.

Sarah Byrne, æt. 22, of delicate appearance, was taken into hospital, February 1st. A week before, she had been suddenly seized with a violent headache, which continued, without intermission, for four days. On the morning of the 5th, she noticed the lids and soft parts round the right orbit much swollen. The following day, she was attacked by a darting pain in the eyeball and deep-seated circum-orbital headache, accompanied with dimness of vision and nausea. On examination, there was considerable œdema of the lids, the globe of the eye itself was prominent; the pupils of both eyes were sluggish and dilated; the conjunctiva of the protruded eye was slightly vascular.

Ordered four leeches to the temple, a calomel and jalap bolus.

3rd.—Feels better; the protrusion of the eyeball still [illegible]; the medicine has caused free action of the bowels. The conjunctiva has resumed a healthy appearance, [illegible]

℞ Pil. Hydrarg.
Ext. conii. aa gr. ii.
Ft. pil. Take one three times daily.

6th.—The eye is much more on a level with the opposite. To continue the pills.

9th.—She now suffers no inconvenience. The eye is entirely restored to its natural level.

FRACTURE OF SUPRA-ORBITAL PLATE BY CONTRECOUP: DEATH.

J. R., æt. 65, a labourer, was taken into hospital, May 6th. He had fallen from a scaffolding in the neighbourhood about 15 feet in height. The fall had been interrupted by a cross beam, against which he struck when half way down. He subsequently fell on his head on a heap of stones, inflicting a severe lacerated wound on the brow of the right side.

On admission the breathing was stertorous; the pupils irregular, that on the injured side being more dilated than the other; pulse laboured, and 60; the man is quite insensible, though giving evidences of pain when stirred; there has been some bleeding from the nostrils.

Ordered an oil and turpentine enema; bleeding to 10 ounces.

May 7th.—The pulse has become more full and frequent; the urine and fæces are passed involuntarily; beef-tea is swallowed in small quantities, when given with the spoon.

10th.—Death occurred this morning after a slight convulsive attack. No change had taken place in the condition of the patient since last report.

Autopsy.—No injury to the bone at the situation of the wound. On exposing the supra-orbital plate, a transverse fracture about its centre, extending across the cribriform plate was discovered. A considerable amount of semi-fluid blood was effused within the dura mater, extending principally up the injured side.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief notes by Dr. Tonge.)

Renal Epilepsey.—Rachel M., æt. 12. Admitted February 9. *Died* on February 10. Subject to headache, but never before had fits; semi-conscious on admission. Recovered in about two hours, but died in a second fit same evening.

Post-mortem.—Brain congested; arteries at base atheromatous; lungs gorged; some patches of pulmonary apoplexy; left ventricle of heart hypertrophied; aortic valves thickened; atheromatous plate in mitral valve; kidneys uneven on surface, cortex thin; deposits of urate of soda in straight tubes; urine in bladder contained one-half of albumen.

Calomel and scammony.

Hysterical Aphonia.—Louisa B., æt. 21, servant. Admitted March 16; discharged May 4; in hospital 49 days. *Relieved.* Lost her voice suddenly 2½ months ago. On admission can only speak in a whisper; has slightly lost power over left leg; pain under left breast. Sour eructations, and occasional vomiting. Catamenia irregular; pulse 100; bowels constipated; partially regained voice.

Quinine, sulphate of iron, sulphuric acid, sulphate of magnesia and chloric ether; asafœtida; valerian and bark. Shower baths.

Pericarditis and Endocarditis.—C. C., æt. 27, smith. Admitted September 17; discharged September 28. In hospital 11 days. *Recovery.* Exposed to great variations of temperature. Previously ill 4 days. Pain in chest and throat. Pulse 52; respiration 20. Area of præcordial dulness increased. Systolic murmur over apex, and occasional diastolic sound at base. No sweating or joint affection. Tongue furred. Free from pain 4 days later. Bruit audible till discharge.

Bicarbonate and nitrate of potass, and aromatic spts. of ammonia.

CARDIAC DISEASE.—J. L., æt. 30, farrier. Admitted June 10; discharged July 9. In hospital 29 days. *Much relieved.* Never had rheumatism. Heart's impulse strong. Apex directly below nipple in 5th intercostal space. Area of cardiac dulness much enlarged. Double bruit. Systolic sound loudest over 2nd right costo-sternal articulation. Pulse 56, very collapsing. Thrill at root of neck, over carotids. Startings at night.

Dilute hydrochloric acid, henbane, and quassia (18 days). Then same, with quinine.

CARDIAC DISEASE.—A. M., æt. 18, tailoress. Admitted October 25; discharged December 14. In hospital 50 days. *Relieved.* Fourth attack of acute rheumatism began 6 weeks ago. Much pain in chest lately. Free from joint pain three days ago. Subject to palpitation and shortness of breath on exertion since first attack. On admission much cardiac pain. Area of heart's dulness enlarged. Loud systolic bruit at apex; faint diastolic bruit at base. Pulse 120; moderately full. Twenty-eight days later slight basic rub (2 days).

Bicarbonate of potass, sp. ammon. arom., and chloric ether. Brandy 4 oz. Dover's powder.

CARDIAC DROPSY.—T. H., æt. 40, commissionaire. Admitted May 10; discharged June 18. In hospital 39 days. *Very much relieved.* Was in King's College Hospital with dropsy in February last, under Dr. Garrod. Dropsy and dyspnœa returned soon after discharge. Orthopnœa 6 weeks. On admission—pallid, legs very œdematous, chest barrel-shaped and resonant; rhonchus and sibilus over lower 2-3rds of lungs; loud double bruit at heart's base. Pulse 90, collapsing; respiration 30. Urine ¼th albumen.

Sesquichloride of iron and chloric ether. Grey powder and colocynth. Turpentine stupes.

REPORT ON WINE AND ITS ADULTERATION.

[SPECIALLY PREPARED FOR THE MEDICAL PRESS AND CIRCULAR.]

No. VII.

IN resuming our Reports on Wine, which excited such wide-spread interest last year, and have only been interrupted by the press of practical matter on our columns, we propose, in compliance with the requests of several of our supporters, before taking up the subject of sherry, to devote a preliminary essay to the methods employed in ascertaining the facts we have to report.

The reader will not have forgotten how large an amount of space we allotted to the question of the amount of alcohol contained in the port-wine of commerce, nor the controversy occasioned by the apologists of the system of *fortifying*, taking up the gauntlet, in its defence, so far as *port*-wine is concerned.

Our investigations have lead to the discovery that sherry wine—the one we shall next take up—is even more constantly adulterated than port, and that the addition of alcohol to even good sherry is carried to a still greater extent. It is therefore natural to consider, first, the mode of ascertaining the amount of spirit in wines. This, accordingly, is the subject of the present number.

The amount of spirit has to be determined by the custom-house authorities, in order to determine the duty payable by any sample of wine; since beyond a certain strength a liquid becomes liable to the duty charged on mixed spirits. This limit used to be 33 per cent. It was advanced, however, to 40 and 45; and now, though said to be unlimited, may be considered practically as 50 per cent. —*considerably more than double the natural strength of wines.*

In estimating directly the strength of wines, the hydrometer is not satisfactory, since various substances present in the wine necessarily interfere with the results. Various other means have been employed, but the most satisfactory of all is the process of distillation. This has been found the most advantageous by the Government officials, and has been uniformly employed in our own experiments. The principle and practice will be readily understood from the following remarks:—

Water, at the ordinary pressure of the air, and on the level of the sea, boils at 212° Fahr., at which temperature it rises as an invisible vapour, and would continue in this state were its temperature maintained unchanged. Passing into the colder air, however, it is manifested as a cloudy vapour, in which state it is commonly called steam, though it consists in reality of very minute globules of finely divided water: steam, properly so called, being invisible, and having all the mechanical properties of air or gas. The visible state is caused by the partial condensation of steam into its original state of water; and a further degree of cold would cause the drops to unite in the liquid form.

On holding a cold plate against the spout of a kettle while the steam is issuing, the surface is first dulled as with a mist; gradually drops of water form, and these again unite and fall, unless the heat of the steam raises the temperature of the plate sufficiently high to evaporate the deposit, when no further condensation takes place. If by any means the coldness of the surface be maintained, the deposit will continue, and in time a quantity of water will accumulate. But this process is both tedious and wasteful; a large portion of steam escapes uncondensed, and a mere fraction of the whole is procured as water. What is obtained, however, is *distilled* water, and is freed in course of the process from any non-volatile impurities that may have been held in solution.

Instead of the mode just described, let the steam be prevented from escaping, and conveyed through a long tube immersed in cold water (such tube may for convenience be bent spirally, when it is called a worm); the whole of the steam will now be condensed, and we shall obtain all the water, purified, as the product of the operation. To ensure complete and continued condensation, the cold water surrounding the tube must be changed frequently, as the amount of specific heat necessary to keep water in the state of steam is sufficient to raise to boiling point a much larger bulk of water than it would itself form when condensed.

Should the water contain in combination anything that will evaporate by heat, both will pass over together, unless the temperatures at which they arise in vapour differ; in which case we have a means of effecting a separation of greater or less completeness, subject to the control of other influences.

This much premised, we pass to the separation of alcohol from water and other matters by the same process, for wines and spirits are all compounds of alcohol and water, the former having in addition mucilaginous, saccharine, and other matters derived from the grape; the latter merely containing small quantities of essential oils and sweetening and colouring matters.

Alcohol pure and entirely freed from water, or anhydrous, is a highly inflammable, colourless liquid, having a specific gravity of ·793811 at 60° Fahr.; it boils at 173°, and rises in vapour. When mixed with water, the compound boils at a temperature intermediate between 173° and 212°, which varies according to the proportion of each ingredient. As the alcohol is more readily volatilized, it rises first; but always mixed *with more or less water.* Hence, by exposing the mixture to heat, and condensing some of the vapour, we can obtain a more concentrated spirit.

Repeated distillation, or better still, a process by which the effect of repeated distillation is produced in one operation, as in Coffey's still, procures a high degree of strength, limited, however, by the extraordinary affinity which alcohol possesses for water, and which prevents our obtaining by this mode a higher degree of strength than about 70 O.P.; beyond this, chemical means must be resorted to. The entire separation can only be effected by the aid of something having a stronger affinity for water than alcohol has. Fresh burnt quick lime is ordinarily used for this purpose, as also many other substances with a like attraction for water ; the description of the process, however, is unnecessary here.

In estimating the proportion of alcohol in wines, &c., by distillation, it is not requisite that it should be obtained pure, nor even in a highly rectified state ; it will be sufficient for our purpose if we get the *whole* that is contained in the quantity experimented on, and free from every other admixture than. pure water. The percentage of proof spirit can then be readily estimated by Sikes's hydrometer.

It is desirable that the process of distillation should be rapidly effected, while it is absolutely essential that the apparatus employed be such as to give exact results.

The simplest and best apparatus we have ever used is that now generally employed in the custom-house, and which we shall therefore proceed to describe. It consists of five principal parts—1, the condenser ; 2, the still flask ; 3, the receiver; 4, the lamp; 5, the stand.

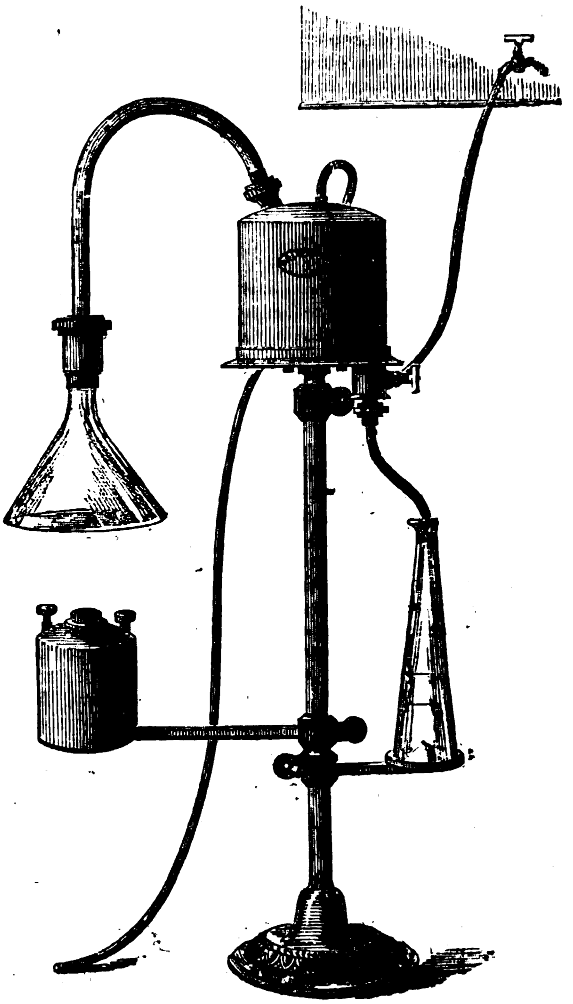
The following figures and description fully explain its use :—

1. The Condenser.—In this the principal value of the instrument consists. It is a copper box made water-tight, about 7½ inches long, 3 inches broad, and 5½ inches deep. Into the upper part of this box two tubes are inserted for the entrance and exit of water, with which it is kept continually full, the supply changing with sufficient rapidity to keep the temperature low enough for the complete condensation of the vapour. Were it not thus changed, it would become so heated with the surplus caloric given up by the steam on being reconverted into water, that the steam would soon escape uncondensed. The tube which conveys the water into the condenser enters at the top and reaches nearly to the bottom ; the other tube only just enters the vessel. By this arrangement the greatest amount of coldness is secured ; as the water, acquiring heat from the condensed steam, becomes specifically lighter than the rest, and rises to the upper part of the vessel, keeping its position above the colder water which enters from below, and passing off first at the exit pipe.

At the end of the condenser, near the exit pipe, a piece of strong metal tube is joined on, inclining upwards for about 6 inches, and then curving downwards in a perpendicular direction, terminating in an arrangement for attaching the still flask, and forming a kind of still-head. This tube, on entering the condenser, is spread out into a broad, flat tube, which continues to descend till it nears the other side of the condenser, when it is folded backwards and then forwards, still slanting downwards, till at the bottom on the further side it connects with a small spout or delivery tube, curving downwards for insertion into the receiver.

The flatness of the tube within exposes a greatly increased surface to the action of the water, and the heat is rapidly absorbed from the enclosed vapour, which is not only reduced almost instantly to the liquid state, but is still further cooled on its passage downwards, so that it runs out at last at a temperature only a few degrees above that of the surrounding atmosphere. The tube by which the cold water enters and leaves the condenser are joined to the main supply and waste pipes by means of india-rubber tubing. It will be sufficient if the cistern from which the water supply is obtained be a yard or two above the condenser.

An improved form of condenser suitable for wine distilling has been brought out by Messrs. Dring and Fage. The principal points of difference are as follow :—The condenser is cylindrical and is so constructed that the bottom is readily removable so as to render repairs of the worm easy. The worm is flat and its width equal to the radius of the cylinder in which it is placed. It is wound spirally round the central axis, and thus forms a screw between the thread of which the condensing water has to wind its way upward to the exit pipe, while the distillate takes the opposite direction downwards inside the worm. The condensation is thus perfect, and the distillate in its descent comes [illegible] continually into contact with a cooler surface, and the whole cooling effect of the water is completely utilised.



2. The Still Flask, or retort, is a conical glass vessel having a thin flat bottom, and a neck at the upper part to which a brass screw is cemented for the purpose of connecting it to the tube leading to the condenser. The bottom of the flask is made extremely thin to allow of the rapid passage of heat to the contained liquid, and render it less liable to break from sudden changes of temperature, while its breadth and flatness expose a greater surface to the action of the flame than in the case of ordinary bulbous retorts.

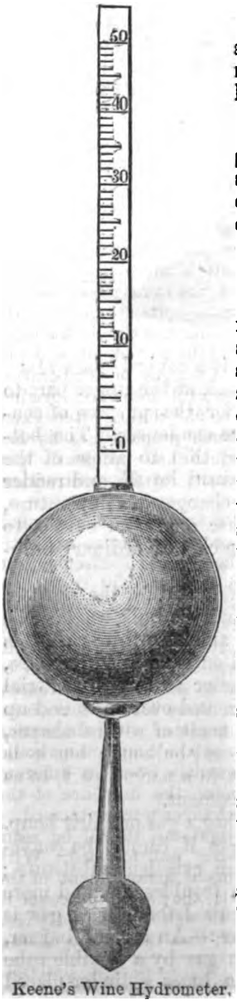
3. The Receiver is a vessel graduated for the purpose —viz., at a point in the neck to mark the bulk used in the operation, and again at one-half and two-thirds of this quantity. The bulk experimented on is no fixed measure, it must suffice to float the hydrometer at zero in the trial tube, and the distillate must be received over and filled up in the same vessel. Receivers are made of several shapes, some tall and conical, others short and bulbous ; but it is necessary to have the upper marks in a narrow part, so as to make it more easy of exact adjustment.

4. The Lamp.—This may be either a gas or spirit lamp. The former is preferable, but where it cannot be conveniently obtained, a spirit lamp is an excellent substitute ; it is, however, more expensive and troublesome, and more liable to accident. In the Custom's Laboratories gas is employed in the following manner :—An argand burner, fixed on a stand, and supplied with gas by a flexible tube for the purpose of mobility, has a brass cylinder placed

round it in the manner in which the glass chimneys are usually attached. This cylinder is open at the bottom, but at the top is covered with a fine wire gauze. On turning on the gas it rises in the cylinder, mixing at the same time in explosive proportions with the atmospheric air which enters at the lower part. This mixture, escaping with reduced velocity through the wire gauze, is ignited on the outside, forming a pale, smokeless flame, producing intense heat. At the same time the flame is prevented passing to the gas in the cylinder below, by that peculiar property of wire gauze which hinders the transmission of flame, and which led to its application by Sir Humphrey Davy to the Miners' Safety Lamp. There are other modes of applying the gas flame equally effective and more economical.

5. THE STAND.—This consists of a stout tubular brass pillar fixed on a heavy base, having a collar at the top, with a screw, by which the height of the condenser can be regulated, that part of the apparatus being screwed to a rod, which works up and down inside the pillar. On the outside, attached by a movable collar and adjusting screw, is a bracket, on which the receiver stands during the operation; and when a spirit lamp is used it can be connected in like manner.

In addition to the apparatus we have described, the following will be required:—A thermometer, which it will be convenient to have narrow enough to enter the flask in which the wine is measured, to take its temperature before the operation, where great nicety is required, otherwise the temperature can be taken in a separate vessel. A Sykes's hydrometer with the movable weights, or which is better in practice, have two separate hydrometers, weighted in the bulbs of the instruments themselves, as 80 and 90 respectively



Keene's Wine Hydrometer.

A far more convenient form, and one that we strongly recommend, has been invented by Mr. Keene.

It simplifies the process very greatly, as will presently be seen, and should be obtained by every one who wishes to follow out such experiments.

Here is a figure of it.

In this very convenient instrument it will be noticed that the scale of divisions is laid down for steps of one per cent. each of proof spirit, rising ordinarily to 50 per cent., that strength being high enough to include the strongest wines imported. In using this with the distillate at 60° Fahr., the exact strength is at once shown by the indications. To meet, however, cases in which that temperature cannot be conveniently obtained, a table is given with each instrument for a range of 11 degrees either side of 60. They are made by Dring and Fage, and sold with their new stills. A trial glass, in which the diluted distillate is poured for testing; and lastly, a pipette or dropping tube to adjust the measurement of the wine and the distillates.

Having now fully described the apparatus employed, we shall, in our next, proceed with a sketch of the process itself.

Foreign Medical Literature.

RECENT CONTRIBUTIONS TO THE THEORY OF THE INNERVATION OF THE HEART AND BLOOD-VESSELS.

(REPORTED BY DR. CHRISTIAN LOVEN.)

Translated from the *Hygiea* for March, 1868, page 112, by

W. D. MOORE, M.D.Dub.et Cantab., M.R.I.A., L.K.Q.C.P.I.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

THE ancient controversy, how far the movements of the heart are dependent on nervous influences from without—that is, from other organs or not—may now be considered as so far decided that the heart must be looked upon as possessing in itself the fundamental condition of its activity. This has been shown from the fact that this organ, even after it has been separated from all connection with the rest of the body, continues to act for a time, which is longer or shorter in animals of different kinds and ages, and in those with cold blood, as, for example, the frog, may, under favourable circumstances, amount to several days. An anatomical complement to this physiological fact, and at the same time an indication for the correct appreciation of this autonomy of the heart, was first obtained through the discovery by Remak, in 1844, of the ganglionic cells scattered in the substance of the organ—an indication which, moreover, was immediately followed up by Volkmann in his well-known theory of the heart's action, as deriving its origin from a number of distinct centres connected with each other, which are to be sought in the heart itself, and especially in its ganglia. This view must now, notwithstanding the opposition of which it has been, and still is, the object, be considered as that most generally received, as it is also in the most complete harmony with the prevalent opinions respecting the physiology of the nerves in general.

But that the heart is, in addition, dependent on the nervous system in general, and on the brain and spinal cord in particular, so that the rhythm and also the intensity of its movements can be directly or indirectly modified through the influence of the central organs just mentioned, is a matter of old standing experience, though it has been reserved for modern times to indicate more accurately the nature of this influence, and the routes by which it is exercised.

The first step in this direction was taken by the well-known discovery of the brothers Ernst Heinrich and Edward Weber in 1845, so important for the theory of the innervation of the heart, that electrical irritation of the part of the brain from which the nervi vagi take their origin, as well as directly of the nerves themselves, relaxes the heart, makes its rhythmical movements slower, and even brings the organ to a standstill. Edward Weber now sought an explanation of this remarkable phenomenon—an explanation so successfully found, that no better can be substituted for it, all others soon failing before closer investigation.

He characterises the influence of the vagus as a restraining action, a nervous function completely without any analogy in physiology, if we consider the nervi vagi as the proper cardiac nerves going to the muscular fibres, and restraint as a result of their direct action on these fibres. We have, however, instances of such restraint of the involuntary action of animal muscles; for example, in the relaxation of the sphincter ani, as well as in the restraining action of the brain on the reflex movements, &c. "But," says Weber, "as in these animal muscles the restraining influence is exercised, not directly through their motor nerves, but in the first instance on the spinal cord, whence their activity is maintained, the restraining influence which the nervi vagi exercise on the movements of the heart, seems not to act directly on the muscular fibres, but in the first place on the nervous apparatus, whence the cardiac movements proceed, and which are here found in the very substance of the heart; therefore, the action of the heart interrupted through irritation of the nervi vagi returns spontaneously, and this notwithstanding that the irritation of the nerve is continued; if, that is to say, in consequence of its exhaustion the motor nerves of the heart, thus freed from the restraining influence of the former, again resume their activity."

This doctrine of the restraining power of nerves, and especially of the pneumogastric nerves, was energetically opposed by some investigators, especially Budge, Schiff, and Moleschott; but was defended and supported with new facts by others (foremost among whom were Volkmann, Ludwig, Pflüger, and von Bezold), and may now be looked upon as fully established.

Ludwig enriched the facts ascertained by the brothers Weber with various new ones, which shed a further light upon the nature of this obscure influence. Thus, he found among other things, that the cardiac pulsations, which occur during or immediately after the irritation of the nervi vagi are stronger than those observed before the same, and from this circumstance, taken along with that already known—that while the heart, in consequence of irritation of the vagus, is quiescent, every mechanical or electrical action on any limited part of its surface, instantaneously produces an energetic contraction of the whole heart—Ludwig drew the conclusion that the nervus vagus certainly prolongs the pauses, but does not weaken the intensity of the motor powers peculiar to the heart, or prevent the recovery of the irritablity ; on the contrary, the action of the vagus seems principally to be through increase of the resistance, which we must suppose hinders the incessant discharge of the impulses constantly developed in the motor ganglionic cells of the heart, and through which the movement, instead of being continuous, becomes periodical and rhythmical, to accumulate, as it were, in these ganglionic cells a larger store of tensive force, which, when it at last overcomes the resistance, exhibits itself in the subsequent more powerful contractions. In such a manner the action of the vagus becomes not properly lowering of, but rather regulating the heart's action ; the work performed by the heart is not diminished, it is only differently divided, fewer but more powerful contractions take the place of more numerous, but weaker ones. But this resistance, which, like a flood-gate hinders the constant outflow of the motor impulses, is produced not exclusively by the nervi vagi, for after their division, and even in the heart taken out of the body, the movements continue to be rhythmical and periodical. Therefore, if the theory of the action of the pneumogastric nerves now described be correct, and everything favours this view, we must assume the existence in the heart itself of a restraining apparatus, whose activity is increased by the nervi vagi, and with which, consequently, these nerves stand in direct connection, or in which their filaments terminate.

A new feature in the question respecting the nature and arrangement of the nervous central organs to be found in the heart itself, is derived from the well-known experiments first instituted by Stannius, and called after him. This investigator in fact observed, that if we tie with a ligature, or cut through with a scissors, the boundary between the sinus venosus and the auricle in the heart of a frog, the sinus just mentioned continues to pulsate, but the rest of the heart stops, after some few strokes, immovable in a state of diastole. If a fresh ligature be now applied, or if a new cut be made in the depression between the auricle and the ventricle, the contractions of the ventricle recommence and continue for a long time, but the auricle remains unalterably at rest. Stannius contented himself with describing the phenomena he had observed, without entering into any explanation thereof; but several other investigators repeated and modified these experiments, and put forward various hypotheses to explain them. To give a fuller account of the controversy elicited by these investigations (between Heidenhain, von Bezold, Eckhard, Bidder, Goltz, &c.) lies beyond the aim of this essay. I shall here briefly allude to only one of the hypotheses in question, which probably has most advocates—that is, Heidenhain's. This is based upon the fact that after the first ligature or incision between the sinus and the auricle, the heart's quiescence, as Volkmann observed, after a time (from five to thirty minutes) ceases, to give place once more to regular contractions; it rests partly, also, on the significant circumstance, that the experiment succeeds most surely if the cut be made with a blunt scissors; but, on the other hand, often fails if it be accomplished in one stroke with a very sharp instrument. From this Heidenhain concludes that the ligature or incision has a stimulating effect on the restraining apparatus, which is probably of a ganglionic nature, placed in the region affected by the operation.

In accordance with this interpretation of Stannius' experiment, the following hypothesis has been suggested to explain the peculiar phenomena characterising the movements of the heart:—In the heart there are two different kinds of automatic or reflex central organs (ganglia) connected with each other—namely, *exciting* and *restraining (regulating)*. In the former, exciting forces are incessantly produced through the normal nutritive process, which are prevented from being incessantly exhausted through the motor nerves in this manner, that in the regulating centres forces are developed, which to such an outflow oppose a certain elastic resistance, which is first, after the exciting forces have attained a certain quantity or tension, overcome by them, and then in consequence of irritation of the motor nerves and the cardiac contraction is produced. At the same time, now the whole accumulated store of exciting force is exhausted, the elastic resistance regains its power, is anew overcome, &c., and a periodical movement is necessarily produced, whose rhythm and intensity must, of course, vary according to the different energy in each of the central organs mentioned, whose irritability may be increased or depressed through different influences affecting them. Further, to explain the regular sequence of the heart's movements, these central organs must be assumed to be arranged and combined with one another in a definite manner—an arrangement, of the details of which we have not, as yet, the slightest knowledge.

Friedländer[1] has recently instituted a series of experiments in von Bezold's laboratory, which, extended and modified, may probably shed some light on this obscure question. The author observed that small portions of the sinus venosus, auricle, and upper third of the ventricle of the heart of a frog, removed with a sharp scissors, continued, in an artificial serum (one part of albumen + nine parts of solution of common salt of 0·8 or 0·9 $^{0}/_{0}$), to pulsate for more than 48 hours, and he even succeeded, by careful preparation, in obtaining small, actively pulsating muscular portions, measuring not more than 0·2 mm. in length, and containing only two or three muscular fibres. Their movements could thus be quite conveniently observed under the microscope. The author now first availed himself of this favourable circumstance to test the view maintained by Schiff and others, that the ganglionic cells were not of any essential importance in the production of the rhythmical movements. It is clear that if any independently pulsating muscular preparation were found, in which no ganglionic elements could be demonstrated, the opinion just alluded to would find therein great support, and the whole of the above described theory of the nature of the cardiac movements would be dangerously compromised. But this was not the case. In order to be able with certainty to discover the ganglionic cells often perceptible, only with difficulty, in fresh preparations, the author employed a peculiar method of colouring with aniline red, and the result of his investigations in this direction was, that in no case could he convince himself of the absence of ganglionic cells in those preparations which had previously pulsated ; usually he could demonstrate two or three, even where in the recent state he should not have suspected their presence.

The pulsations of small muscular portions varied both in frequency (between 2 and 40 in half a minute), and in intensity; indeed different portions of the same preparation—in size not amounting to half a mm.—often exhibited the greatest varieties in the rhythm and strength of the contractions. Gentle mechanical influences increased the movements and produced them when they had ceased. Changes of temperature were found to have a particularly powerful influence, gradual or sudden warming up to from 86° to 95° Fahr., often exciting the most active movements in such preparations as had not before pulsated, and in those which had previously pulsated, both the number and the intensity of the contractions were greatly increased.

Lastly, the author employed also irritation of the small preparations of the heart with an ordinary electro-magnetic induction-apparatus, and observed the different effect in different cases. Thus, at one time the frequency of the movements was increased, and this was usually the case; at another, on the contrary, the induction-stroke had no effect upon it, although the intensity of the contractions was augmented ; in other instances again, the author saw distinct diminution of the number of the pulsations (even to diastolic quiescence), and he considers that he may explain these latter as *restraining phenomena* on this account, that together with diminution of frequency an increase of intensity of the contractions could be distinctly observed. Not unfrequently even, in different parts of the same preparation, under the influence of the electrical current, all these various changes were witnessed.

The results of the author's investigations, it will be seen, agree well with the hypothesis above put forward. With respect to the question of the anatomical arrangement of the special exciting and regulating ganglia, they seem moreover to indicate, that these central organs, though so differently constructed, often lie so near one another, that the actions charac terising them may at once exhibit themselves in preparations of the smallest dimensions.

---

[1] *Ueber die Nervösen Centralorgane des Froschherzens* in Untersuchungen aus dem Physiol. Laborat. zu Würtzburg herausgegeben von A. v. Bezold. Bd. II., p. 159.

E. Cyon[1] has instituted in Ludwig's laboratory, and with particularly ingenious apparatus and methods invented by him, a series of investigations upon the changes exhibited by the movements of the heart of the frog under the influence of different temperatures, which incontestibly belong to the best and most reliable researches upon this subject. Without being able to enter in this place into any more accurate description of the very complicated apparatus employed in these experiments, I shall give a brief account of its plan and object. A circulating system of glass tubes was passed on one side into the left aorta, on the other into the vena cava inferior. This system of tubes, which, as well as the heart itself, was filled with fresh serum of rabbits' blood (dogs' serum was found to act as a poison upon the heart of a frog), communicated with a small mercurial manometer, which, by means of a so-called "float," marked the heart's pulsations, as on an ordinary Ludwig's kymographion, on a cylinder rotating with uniform rapidity, in the form of curves, distinguishing both the frequency, course, and intensity of the pulsations. The heart, with its artificial vascular system, was included in an atmosphere, which could easily be brought to the desired temperature. In this apparatus, as the reporter, who was at the time working in the same laboratory, had the opportunity of satisfying himself, the heart continues to pulsate for more than 24 hours, provided that the serum is now and then drawn off and replaced with fresh.

The author's investigations comprise two different series namely, A, the effects of a gradual change of temperature; and, B, those of sudden alterations of temperature.

A.—1. *Change of frequency of the pulse with the temperature.*—The author commences by confirming Schelske's observation, that the heart of the frog maintains its power of automatic action only within certain limits of temperature, of which the lower lies between 24·8° and 32° F., the higher varies from 86° to 104°. A diagrammatic curve, exhibiting the comparative frequency between these extremes, ascends from the lower limit, at first very slowly, and afterwards more rapidly, to a temperature where the maximum of frequency is attained, and subsequently falls some degrees at first slowly, but afterwards so rapidly, that if the heart is merely warmed some few degrees more, it remains perfectly at rest. Under the two or three degrees which precede the quiescence of the heart, the latter beats not merely slowly, but also irregularly, and immediately before the quiescence the motion is peristaltic, the ventricular fibres contracting at different times. The maximum above mentioned falls in different hearts at somewhat different degrees of temperature ; as also a number of individual circumstances act on the appearance of the curve in particular cases. As a definite result it may, however, be stated that elevation of temperature within certain limits considerably increases the frequency of the pulse—a welcome fact for those physicians who believe the acceleration of the pulse in fever to be caused by increase of temperature.

2. *Alteration of the volume of the contraction.*—In this respect a very definite law seems to prevail, which is best exhibited in the same manner as the frequency of the pulse—namely, by a curve, whose absciss represents the temperatures, and whose ordinates correspond to the intensity of the contractions. Such a curve exhibits here, also, a maximum and two minima, which latter lie at the superior and inferior limits of temperature, where the heart, as above mentioned, ceases to beat. But, in opposition to the cause of the frequency of the pulse, this ascends so rapidly from the lower limit of temperature, that even only some few degrees above zero it attains the maximum, keeps usually at this height to about from 59° to 66·2°, and sinks afterwards uninterruptedly to the superior limit of temperature. At the degrees of temperature immediately preceding this, we observe the peculiar circumstance that the heart is still engaged in active contractions without exercising the slightest effect on the manometer. This depends upon the fact that the contractions are peristaltic, and therefore cannot overcome the external resistance, as the parts of the heart which do not contract are dilated, just as much as those which contract are compressed.

3. *On the relation between the volume and the frequency of the pulsations of the heart.*—From what precedes it appears that, with increase of temperature from zero to a certain limit, the frequency of the contractions uniformly increases, while their intensity remains unaltered. In the interval of temperature immediately next following, the frequency continuously increases, but the intensity sinks until the temperature is passed, at which the heart's pulsations have attained their maximum of frequency, after which both frequency and intensity diminish until they become *nil*. These facts show incontestibly that the relation between the intensity and the frequency of the cardiac pulsations cannot be explained from a simple principle; in a word, that no necessary connection exists between these two elements.

4. *On the course of the contractions of the heart.*—In this respect different hearts do not all behave in the same manner. At one time we see the curve which represents the pulsation of the heart rapidly ascending and almost immediately sinking, at another rapidly ascending and sinking with tetanic points, at another again rapidly ascending with a sudden transition to a state of diastole, which is gradually terminated; at another, finally, slowly ascending with a gradual transition to diastole, and then slowly sinking. Even in one and the same heart the course of the contractions varies at different temperatures, and this in general, so that with a diminution of temperature the ascending and descending parts of the curve are drawn out in length. According to the author's view, all these varieties are easily explained as depending on different conditions in the nerves and muscular fibres, and not on peculiarities in the stimulating apparatus. Supposing, in fact, that, as Marey does, we may look upon the pulsation of the heart as a single muscular contraction—an opinion in favour of which many cogent reasons may be adduced, though there are also various difficulties, which may, perhaps, be regarded as depending on the peculiar structure of the cardiac muscles.

5. *On the work which the heart can perform in each unit of time at different temperatures.*—If authors would always employ the same manometers of known dimensions, and the same serum for each separate heart, the work accomplished by each cardiac pulsation might, if the question were only as to the relative value, be easily calculated from the weight of the pillar of fluid driven into the manometer, and thus the work accomplished by the heart in a certain unit of time might be calculated by multiplying the said value by the number of pulsations. In this manner the author found that the maximum of work was accomplished by the frog's heart, generally between 64·4° and 78·8° F.

6. *On the quantity of the motor impulses, which at different temperatures proceed from the automatic centres.*—As a relative measure of this quantity, we may in general employ the magnitude and duration of the muscular contraction, provided always that the impulses to be compared with one another have acted on equally irritable and similarly loaded muscles. In view of the difficulties which in the present case attend such a determination, we must be satisfied with only imperfect indications. Thus, it is impossible positively to decide whether the sum of the impulses is increased or diminished, when the temperature sinks below 64° F., because therewith the work performed by the heart is certainly diminished, but at the same time, also, the muscular and nervous irritability is considerably lowered. On the other hand, we can with full certainty conclude that it is diminished for every degree above the mean temperature (64·4° F. to 78·8°), for there, as is well known, the irritability of the nerves and muscles increases, but nevertheless both the duration and the volume of the several contractions are lessened.

7. *Of the adaptation of the number of the motor impulses to the state of the muscular mobility.*—Every transversely-striated muscle, the heart not excepted, requires, when its temperature is greatly lowered, a long time to perform its contractions. Now, if at the lower degrees of temperature the heart were stimulated as often as at the higher, it would unconditionally lapse into tetanus, because the one contraction would not have passed off before a fresh one had begun. To explain the adaptation which here undeniably takes place, we might be inclined to assume such a connection between muscle and nerve on the one hand, and the stimulating apparatus on the other, that a fresh stimulus could not act until the previous contraction had terminated. Various facts observed by the author would, however, bear most decidedly against such a view, and therefore no other mode remains of explaining the phenomenon than to assume that both the exciting centres, the nerves and muscles, are uniformly affected by the temperature; that therefore the circumstances which increase or diminish the mobility of the nervous and muscular molecules, have one and the same action on the exciting apparatus.

8. *Of the change of the elasticity of the cardiac muscle at an*

[1] *Ueber den Einfluss der Temperaturänderungen auf Zahl, Dauer und Stärke der Herzschläge*, von Dr. E. Cyon. Arbeiten aus der physiol. Anstalt zu Leipzig vom Jahre, 1866 mitgetheilt durch C. Ludwig.

increased temperature.—In this respect the author found that the extensibility of the heart is considerably increased at an augmented temperature, which is manifested by the fact that the quicksilver in the manometer sank at the higher temperatures during the diastole, several mm. deeper than at the lower, and this was especially apparent if the dilatation of the heart were compared when it stood still at the upper and lower limits of temperature.

B. *Effect of sudden changes of temperature on the impulse of the heart.*—This appeared to be totally different from the effect of gradual change of temperature. The results of the author's experiments were briefly as follow:—1. If the heart, previously pulsating at a temperature of from 68° to 71·6° F., is suddenly brought into contact with serum or air at 32°, the deviations of the manometer are diminished, the movements of the heart become peristaltic, and the heart is dilated in a higher degree than is usually the case in gradual transition to this low degree of temperature. After some minutes, the movements again become greater, and the heart subsequently behaves as when it is slowly cooled. 2. If a heart, which has for a long time been kept at or below the freezing point, be suddenly brought in contact with serum or air at 104° F., it performs a series of strokes following so rapidly on one another, that it finally passes into a state of complete tetanus, which is evidently produced by the impulses following so closely on one another, that one contraction does not terminate before the next commences. This tetanus may continue for from fifteen to thirty seconds, and subsequently the heart runs through all the forms of pulse, which it usually exhibits when slowly heated. 3. The state of the heart is again quite different, if from the normal temperature it be suddenly exposed to 104° F. In contrast to the foregoing, and to its condition in slow heating, the beats now become strong with long intervals, and precisely resemble the form of pulse obtained by irritating the nervi vagi at the normal temperature. After the lapse of one or two minutes, the heart once more passes through the above mentioned intermediate stages, characteristic of slow heating. 4. A heart which has been poisoned with curare differs from one not poisoned, insomuch as the former, when suddenly heated from 68° to 104° F., does not exhibit the strong pulsations separated by long pauses, but behaves precisely as in slow heating.

This dissimilarity is explained by the fact that curare, according to Heidenhain's experiments, confirmed by Czermak and by the author, annihilates the irritability of the nervi vagi, and this observation therefore supplies a powerful reason for the assumption that the phenomenon mentioned in 3, depends on an irritation of the termination of the vagus in the heart.

The author concludes his essay with an attempt to explain the phenomena observed, by the above mentioned usually received hypothesis respecting the nervous apparatus of the heart.

When the heart is gradually cooled from the mean temperature to the freezing point or below it, the power of the restraining apparatus must, within the interval, in which the frequency of the heart's pulsation, but not its intensity, is diminished, have increased, and likewise the motor impulse causing each stroke of the heart must have grown stronger, while at the same time the irritability of the nerves and muscles is diminished by the lowering of the temperature.

The phenomena which occur on slow warming from the mean temperature to the degree of temperature at which the heart exhibits the maximum frequency of pulse, indicate that the forces in the exciting and restraining centres at the same time diminish, because the work therewith performed by the heart is lessened. The arrest at the superior limit of temperature must be caused by this, that the stimuli developed are not sufficient to excite the muscles to contraction, for in this case, as is well-known, the nervous and muscular irritability is in general increased, which, in this instance also, is proved thereby, that the weakest mechanical or electrical stimulant produces a pulsation of the heart.

But that during arrest in warmth the irritability of the regulating apparatus also is almost removed is shown by this, that local irritation of the sinus venosus then produces complete tetanus in the ventricle, which continues as long as the irritation lasts.

By this, the condition in which the heart is found during this arrest is distinguished from all others, for at the mean temperature, irritation of the same place through excitation of the vagus infallibly produces an arrest of the heart in diastole, and in the absence of movements which characterises the lower limit of temperature, such an irritation produces merely a single contraction, but no tetanus. Hence too the opinion already put forward by Schelske acquires great probability—namely, that at the high temperature spoken of, all the apparatuses, which otherwise can modify the results of an external irritation have ceased to act, or in other words, that both the organs which *generate*, and those which *co-ordinate* the motor impulses, have fallen into a kind of trance. As to the sudden change of temperature it seems to act principally as an irritant, and in the first place upon the vagus.

The author remarks, in conclusion, that though his investigations, which were rather calculated for a general review, may not be considered as an experimentum crucis for or against the current hypothesis, they may however lead us to hope that by accurate special studies in this direction, we may arrive at results important in their bearing on the theory of the heart's action.

(To be continued.)

Literature.

LECTURES ON CLINICAL MEDICINE.[1]

In our number for the 6th of November, 1867, we briefly reviewed the third and concluding part of the first volume of Dr. Bazire's translation of Trousseau's admirable lectures, so that we need not again enter on a description of them, or of Dr. Bazire's well and faithfully executed edition of the English version of them.

The eminent French teacher and his brilliant and industrious pupil have been both called to their rest, leaving the English work of the latter incomplete. Such being the case, the New Sydenham Society—very properly, we think—took up the continuation of the translation, and, in order that whole might be published uniformly and in their usual style, they decided on reprinting vol. i., which had been just before Dr. Bazire's death, and of afterwards continuing the work which that lamented physician left unfinished.

The volume before us is, then, a literal reprint, not a new edition, of Dr. Bazire's work, and as such we hail its appearance with pleasure.

It is scarcely necessary to add that the "get-up" of the volume is in the usual and favourably-known style of this most useful Society.

THE LATE DR. ADDISON'S WORK.

In this case,[2] as in that of Trousseau and Bazire, we need not introduce to our readers the classical name of Thomas Addison, or give any description of or criticism on his writings, which are known to most well-read, modern physicians, and which enjoy so solid a repute as to have induced the New Sydenham Society to publish them, as they have done, among the medical classics of the nineteenth century.

This volume consists of 242 pp. 8vo, and is opened with an editorial biography of Addison, which shows how hard work and unceasing determination did not fail to place him in that position which he was ambitious to fill, and which he did fill with such distinction and usefulness.

Prefixed to the first five papers on diseases of the lungs is an excellent editorial preface. No. 6 is entitled, "Observations on Fatty Degeneration of the Liver," No. 7 "On the Disorders of Females connected with Uterine Irritation;" No. 8 records a "Case of Ovarian Dropsy removed by the Accidental Rupture of the Cyst;" and No. 9 is a reprint of a celebrated paper, well-known in connection with Addison's name: "On a certain affection of the skin, Vitiligoidea—(*a*) Plana; (*b*) Tuberosa."

No. 10 is also a well-known original contribution to medical science—"On the Keloid of Alibert, and on true Keloid." No. 11 treats of "Disorders of the Brain connected with Diseased Kidneys;" and No. 12, "On the Influence of Electricity as a remedy in certain Convulsive and Spasmodic Diseases."

The last paper—No. 13—is perhaps that with which Addison's name will be best known to medical posterity, and is entitled, "On the Constitutional and local effects of disease of the Supra-renal Capsules." Beside his own preface, the editors have also prefixed one. Of course we need say nothing to our readers about "*Morbus Adissonii.*" This collection of Addison's papers is an admirable publication. Addison never wasted words; and so he, being dead, yet speaketh.

ARMY MEDICAL OFFICERS.

ARMY medical officers have some real grievances. They complain of the restriction under which, as compared with the combatant ranks, they obtain leave of absence, either on private affairs or on the recommendation of a Medical Board, when serving in foreign stations; and of the extremely short time they are, as a rule, permitted to remain in the United Kingdom between the completion of one term of foreign service and the commencement of the next. That there exists a desire on the part of the present Director-General to improve the position of his officers in both respects, there connot be a doubt. We really do know of a few very fortunate men who have of late returned to this country on what is called *private leave*, but we are no less aware of the utter hoplessness of a medical officer, other than in very exceptional cases, obtaining this boon, at the same time that the *battalion* officers of his own regiment obtain the indulgence almost, as would appear, without limit. With regard to *sick leave*, the medical officer is still more disadvantageously placed. A surgeon of a regiment, and a major in the same corps, for example, arrive in England from abroad, both "to appear before a Medical Board." Both have suffered from liver, or dysentry, or cholera, and the severity of the illness is as nearly as possible alike in both. The surgeon obtains three months' leave, the period being too short to permit him to fairly settle down into that regimen which is necessary for the restoration of health. At the expiration of that time he, perhaps, get an extension of other three months, but if, at the end of that period, his health should happen not to be restored, he knows perfectly that he must submit to being deprived of his regiment, in order that he may, in the words of a late Director-General, "make way for a more efficient medical officer." But this is not all. In the event of his health not being so completely broken as to render him totally unfit for work, he is placed upon duty at a home station, and, at the same time, in the roster for foreign service; but if so completely used up as to be fit for nothing, is shelved on *half-pay*. Not so with the major however. What is in this supposed instance sauce for the goose, is by no means sauce for the gander. He that is the major, has, in all probability, obtained six months' leave at at one fell swoop. He then obtains six months more; then an extension, and so on for eighteen months or a couple of years; and then, when convenience and season suit him, rejoins what is still *his* corps, but in which the name of the surgeon is all but forgotten, it is so long since he left it.

Now, if our views are correct, there are abuses both ways here. If the sauce be of Normandy pippins in the one, let it not be of crab apples in the other. And so, as regards home service. Regiments, as a whole, are supposed to spend five years at home for every ten they are abroad. Officers of the Royal Engineers make arrangements, as a matter of course, for five years at a home station; and so on with other "departments," save and except the medical officers in all ranks of which can seldom reckon upon more than a few months, or at most a year in England.

The reason assigned for all this, is that "the estimates" limit the numbers of medical officers to their present standard; and that really the *roster* comes round so rapidly that the existing evils are unavoidable under the system.

Precisely so! But ought not a system which works so unequally, and often so injuriously, be modified? Undoubtedly it ought. Let the officers most concerned, therefore, use their best endeavours to return to a Parliament a member pledged to support and advocate their interests as a department. If the present numbers of medical officers are insufficient for all the duties required of them, the interests of the service demand that they be increased.

◆

Notes on Current Topics.

Medical Honours at Oxford.

OUR great educational nursing-mother at Oxford has followed the example of her humbler sister in Dublin in its honorary rewards to the eminent members of the profession who have visited her walls this year, and has laid the hand of approval on the heads of six men worthy of every honour in her power to bestow.

Not only medical eminence, but great talents and indefatigable perseverance in the pursuit of science, have been rewarded in the persons of the gentlemen selected for the Honorary D.C.L. No one can say that Sir Charles Locock, the Rev. Dr. Haughton, Dr. Gull, Mr. Paget, Mr. Simon, and Mr. Syme are mere physicians or surgical handicraftsmen. They are men within whose minds there is room for greater considerations than money-getting practice, and it is a noble assurance to those competitors who labour for celebrity in the widest fields of medical science, that such men are not only successful practitioners, but are thought worthy of the highest praise our greatest University can give.

Nomenclature of Diseases.

WE are glad to report that the new nomenclature of the London College of Physicians, of which we have already given some particulars, is now ready. It will be adopted by all the public departments, and no doubt will shortly be recognised as the standard Nomenclature of Diseases. The College will, we suppose, present a copy to every fellow and every member on application, as was the case with the report on leprosy. We hope other medical men may be able to purchase the book at a low price. The College has no longer its pharmacopœia to produce, but a work of this kind may very well absorb its energy. There can be no reason either why some day a small profit should not accrue. If we think how many thousands of copies might be sold at a very low price, there is ample room for this. No publisher need be employed to take his large profits, but the College could sell at one uniform rate direct to the purchaser. The post would distribute it in a rapid and economical manner through the country. In London the purchaser could send to Pall Mall for it. We really see no reason at all why the College should not thus take advantage of its production in this way. At any rate, it might recoup the heavy expenses of getting up such a work. The book, too, like a pharmacopœia, will need revision, and the College already contemplates that contingency, and will be prepared after ten years with a revised issue.

This first attempt at a universal nomenclature in Latin, English, French, Italian, and German, is a work worthy of the learning and traditions of the Royal College of Physicians of London.

Sir James Simpson.

THE profession will shortly receive, in the person of one of its greatest obstetric representatives, a very unusual honour. It is seldom that eminence in our body receives a direct public and extra professional recognition, for very few medical men can afford to take such a part in the administration of the commonwealth as to render them suitable claimants for public honours. Sir James Simpson is to receive the freedom of the city of Edinburgh, and the honour is enhanced ten-fold by the fact that, in its conferring, he is to stand side by side with Lord Napier, of Magdala. Such a compliment at the hands of the Representative Council of the chief city of Scotland is an unequivocal proof of the estimation which Sir James has obtained in his private and local capacity, and amounts to a declaration that a medical man, who may prove himself deserving of public reward, is in no respect incapacitated from receiving as full a measure of honours as the most esteemed and worthy of the servants of the Empire.

The late Mr. Travers.

WE regret to have to notice the decease of Mr. Benjamin Travers, F.R.C.S., who bore through a long life most worthily the illustrious name he had inherited. If he ever had an enemy it must have been in his youth, and the feeling could scarcely survive. The almost sneering manner in which one periodical has spoken of the deceased is therefore particularly obnoxious to censure. The person who penned that paragraph has evidently no notion of greatness except such as consists in making great incomes. What an ignoble test of a professional life. The writer who applies it does not deserve to have any connection with the medical profession.

The Cattle Plague.

OUR congratulations on the entire annihilation of the cattle plague throughout the empire must be tempered with the recollection that its ravages extend much closer to our coasts and the sources of our import trade than we could wish. It has broken out with great violence in the districts of Heyde Kong and Goldup, in Prussia, and in the Tyrol, and the most active precautions are being enforced to prevent its spread. It is to be hoped that our official guardians will hold themselves on the alert against the importation of any cattle from these districts within our coasts.

Sunstroke.

THE exceptional heat of the weather this summer has excited unusual interest in the phenomena of sunstroke, and the prevention of this formidable malady, and its treatment when it appears alike deserves renewed attention.

It should never be forgotten that rational precautions seem almost always to be successful. In this country sunstroke ought to be not only rare but unknown. Protect the head and nape of the neck, wear loose clothing of proper material, and avoid stimulants—those are the cardinal rules for prevention.

How is it that the British gentleman cannot be persuaded to discard his absurd chimney-pot, and take as a head-dress any light-coloured and broad-brimmed cap? The ignorance and folly prevailing on these points astounds many. As medical men we ought to set a good example, and teach our patients to emancipate themselves from the thraldom of fashion. Some are ready to do so, but hesitate to go against established usage. The boldest reformers stop half way.

We lately met in Piccadilly a physician, whose name is well-known, walking in a white silk alpaca loose coat. He had been to visit his patients in that attire, and confided to us that they all complimented him on his courage; but even he had on his chimney-pot hat, although wise enough to use his umbrella as a parasol. The same day we met another physician walking about London in a Panama hat. He said, "What is the use of brains if we dare not use them?" We repeat his query, but we may add that to arrive at a proper dress for such weather as we have had it would be necessary to combine the courage of these two bold reformers.

So much for prevention. As to cure, Indian officers place most confidence in the douche to both head and shoulders. The best account of sunstroke we have met with is by Dr. Maclean's essay in Reynolds's "System of Medicine," the most remarkable collection of original medical memoirs produced in this generation. To that learned work we accordingly refer our reader for information of the most trustworthy kind.

Junior University Club, Dublin.

THE provisional committee of this Club have issued a circular, in which they announce that their exertions for its establishment have been attended with very fair success—such as to lead them to the conclusion that they may anticipate large support from the University Graduates throughout Ireland. The Club will be available for *alumni* of any University of the United Kingdom. Premises have been secured in the neighbourhood of Dawson-street, and it is hoped that accommodation will be available for the members by the 1st of October next.

The Plague of Flies.

THE activity of insect life, consequent on the recent tropical heat, has as yet only made itself manifest to the body corporate of the individual Englishman, but it appears from the correspondence of our contemporaries that more serious results are to be feared in the destruction of crops by the enormous multiplication of such depredators.

Against such a result we must look for help to our native small birds, and we may yet feel the punishment of the unreasoning slaughter of our natural protectors.

The sparrow clubs, which have hitherto been simple and comparatively inocuous aggregations of rural blockheads, become now absolutely hostile to the public gain, and it is to be hoped that the emergency may induce them to suspend operations until the plague of flies, which threatens our island, is neutralised.

Bathing.

The Royal Humane Society have followed up their valuable circular of directions for the resuscitation of persons apparently drowned, by a further paper drawn up by Dr. Sieveking and Professor Christison, on the subject of bathing. Though less within their function, the public are none the less under obligation to the Society for information which no one has thought of giving them elsewhere. The following, in substance, are the suggestions of the Society :—

Not to bathe until the stomach is empty ; at least two hours after a meal.

Not to bathe when the system is debilitated by unusual fatigue.

Not to bathe when the skin is in a condition of perspiration, or immediately afterwards, but when the surface of the body is warm.

Not to bathe when chilliness is felt, nor to cool down the body by standing naked *either before or after* bathing.

Not to bathe at all if a short stay in the water, under the above conditions, be habitually attended with chilliness or numbness of the hands and feet.

Not to bathe, if the system be weakly, early in the morning, when the system has been many hours without support, but, if possible, about three hours after breakfast.

Pepsine Biscuits.

Messrs. Bewley and Hamilton, of Dublin, have recently introduced to the notice of the profession biscuits prepared by them with the view of providing an agreeable and eligible form for the administration of pepsine. Each biscuit contains 5 grains of pepsine, so that two or three may be eaten before a meal. They are put up in ¼ lb. canisters, containing twenty biscuits. In this preparation the pepsine is administered in a perfectly unobjectionable form, for they differ in no respect from ordinary wine biscuits, and are devoid of any objectionable flavour whatever.

◆

THE BRITISH MEDICAL ASSOCIATION.

The meeting of the profession at Oxford which has been looked forward to with much interest, took place since the publication of our last issue, and may be pronounced to have been an entire success. The arrangements usual at all the meetings of the British Medical Association for the provision of information and accommodation were efficiently carried out, and several of the colleges opened a portion of the apartments at their disposal for the reception of the visitors. The very great length to which the addresses and communications run, prevent us from doing more than abstract their most important parts.

The inaugural meeting took place on Tuesday evening at eight o'clock, in the hall of Christ Church, and was so largely attended that it would be impossible for us to attempt an enumeration of the members present. The chair was taken by Dr. Stokes, Physician to her Majesty the Queen in Ireland, and the outgoing President of the Association, who proceeded to deliver his valedictory address.

The President, after some preliminary observations, said, let me, before bidding you farewell, say a few words as to the future of this great Society—now the most numerous body working for the benefit of science in the world, and which will doubtless attain to large dimensions. So far, we have been an united body, which is to be attributed to our federal constitution, with independent local action, and a representative and imperial executive. How long this strength giving union may last no man can predict ; nor, on the other hand, can any man say to what an amount of influence for good this Association may attain. But it is plain that its durability and usefulness will depend on its being made the instrument for the public good, rather than the machinery to advance the immediate worldly interests of the profession. And everyone of us must lay it to heart that a great issue rests within his hands. The man among us who by his unselfish labour adds one useful fact to the storehouse of medical knowledge, does more to advance its material interests than if he had spent a life in the pursuit of medical politics. Far be it from me to say that there are not great wrongs to be redressed. It is impossible, in any country, that evils of custom and of administration, private wrong, corporate shortcomings, hard dealings, unfair competition, and scanty remuneration for public and private services should not occur. But these evils being admitted, how are they to be lessened, if not removed ? Is it by public agitation and remonstrance, addressed to deafened or unwilling ears ? Is it by the demand for class legislation ? or is it, by the efforts of one and all, to place medicine in the hierarchy of the sciences in the vanguard of human progress; eliminating every influence that can lower it, every day more and more developing the unprofessional principle, while we foster all things that relate to its moral, literary, and scientific character. When this becomes our rule of action, then begins the real reform of all those things at which we fret and chafe. Then will medicine have its due weight in the councils of the country. There is no royal road to this consummation. On the one hand, the liberal education of the public must advance, and the introduction of the physical sciences in the arts courses of the Universities, has given the death blow to empiricism; and, on the other, that of ourselves must extend its foundations, and trust far less to the special than to the general training of the mind. When medicine is in a position to command respect, be sure that its rewards will be proportionally increased, and its status elevated. In the history of the human race, three objects of man's solicitude may be indicated: first, his future state; next, his worldly interests; and lastly, his health. And so the professions which deal with these considerations have been relatively placed; first, that of divinity; next, that of law or government; and, as man loves gold more than life, the last is medicine. But with the progress of society, a juster balance will obtain, conditionally that we work in the right direction, and make ourselves worthy to take a share in its government, not by coercive curricula of education, not by overloaded examinations in special knowledge, which are, in comparison to a large mental training, almost valueless; but by seeing to the moral and religious cultivation, and the general intellectual advancement of the student. Doubtless, such a revolution, which, could men only read the signs of the times, is slowly, though surely, coming, will lessen the number of a certain order of candidates for license to practice. Doubtless, also, while the funds of special corporations will be diminished, university education will be extended; and the whole character of medicine will be changed, greatly to the advantage of its social position in the country, and the interests of science and the public at large.

Putting aside the success of your labours at Dublin, in a scientific point of view, your meeting of last year deserves a long remembrance. It was the first occasion on which the members of all ranks of British and Irish professional men met to know one another, to unite in the common cause of the advancement of knowledge, and to learn, on a great scale, how the mutual cultivation of science will efface national prejudices ; for it is only in this way that those national dislikes and distrustings which become hereditary feelings, transmitted from one generation to another, which separate peoples and delay the peaceful federation of the world, can ever be removed. The star of knowledge, while it illuminates the path to wider and still wider discovery, yet is like unto that which guided the sages of the east to the cradle at Bethlehem ; for its benignant light is the herald of peace and good-will among men.

Dr. Stokes's observations were received with vehement applause, which was renewed on the assumption of the chair by Dr. Acland, the President, who proceeded to deliver the inaugural address.

Having spoken warmly of the success of the visit of the Association to Dublin—The President said,—We are living in a critical period of our country's history; in a new era in the history of man. Every part of our social fabric is now undergoing scrutiny, revision, and reform. Government, trade, institutions, laws, the artificial usages of society, the character to be given to our children by the method of their early training, are not only being criticised, but are most of them being changed—changed with unexampled rapidity; and the change is, some think, a tendency to absolute perfection, or, according to one philosopher, a last plunge down the Falls of Niagara. The facility with which ideas are communicated through the whole human family, distinguishes our age from all that precede it. Our own profession is not exempt from these influences ; even if it were, we are part of the body politic, and, as wise men, we might do well to look forth from the fretted shelter of this ancient hall, itself a memorial of the ferment of the Reformation, and, watching the storm as it drifts along, take the bearing of our own course in the stream of time. I propose to take a general survey of the position occupied by our professional knowledge in relation to other branches of knowledge, and to consider the objects which ought to be held in view when we discuss the temper required of us by our times, and the training proper for the formation of that character and temper.

Now, in judging of the medical character, we set aside, of course, all reference to individuals. We form an ideal character. And yet the ideal cannot be considered wholly in an abstract way. We have to judge of it in its relations—first to the condition of Science, and secondly to the constant properties and the variable accidents of Humanity. In the present age, science is advancing, and the means of its progress are increasing with altogether unexampled rapidity. No bounds can be set to its possible conquests. A profession dependent on science must vary with that on which it depends; and if it does not advance with the advance of science, that fact proves it to be in error. Humanity has its constant properties and its variable accidents; its constants of need of food, of warmth, and of clothing; its constants of sickness and disease; its constants of relative poverty and relative wealth ; its constants of yearning after good, and exposure to misery and guilt. But humanity has also its variable accidents of climate, of fashion, of ease, of luxury, of degradation; not, like death, unavoidable and irremediable, but accidents, terrible acidents—such as, however formidable and perilous, to a certain extent may be avoided or can be remedied. Reflection will show to what a vast range of subjects medicine is linked by these two circumstances, the progress of science and the fluctuations of humanity. How numerous are the points of science which touch us more or less closely.

Let us then consider, first, the relation of modern medicine to modern science. It was just now said that medicine is necessarily linked to the existing condition of science. This statement must be examined more closely. Medicine is at once in advance of the exact sciences, so-called, and behind them. It is in advance of them, inasmuch as it clinically observes as facts some things which science has not yet fully explained; and it believes with strong conviction what can at present be neither demonstrated nor ignored. It is behind them, inasmuch as they claim for every fact of science an exactness to which medicine cannot always pretend. But medicine too long consented to regard itself as an art as distinguished from science. Now, the existing relations of pure science and medicine are both direct and indirect. In the direct relations it follows the lead of science without hesitation ; in the indirect relations it cannot afford always to wait for positive instructions. Let us look for a moment at each of these relations. The relations are direct in the case of all those means of modern invention and research which are applied daily, in ways of which half a century ago there was no conception, to the discovery and the explanation of physiological and pathological phenomena. To the interpretation of sounds heard within the body, Laennec and a host of subsequent observers brought precise acoustical observation and experiment, and showed us how to map out the condition of external parts, the action of which we hear but cannot see ; so that though we are not always able to say absolutely what is the nature of an abnormity, producing an abnormal phenomena, we can at least say what it is not. By applications of optical instruments Czermak and Cruise have laid open to us many organs of the body before inscrutable—the pharynx, the vocal chords, the trachea, the vagina, the uterus, the bladder ; so that the actual but hidden causes of many phenomena are no longer matter of argument, but of sight and demonstration. The secrets of the eye, I need not say, are now disclosed by means of the physical contrivances of Helmholtz and others, assisted by the many elucidations contributed by our own countrymen. Albutt and Ogle in this country, and others on the continent, are working out the further proposition that some states of the eye are not only important in themselves as local abnormities, but as being pathognomonic of other suspected conditions in other and distant organs. The sense of touch is so supplemented by the skilful apparatus of Marey that the wave phenomena of the pulse and heart are registered ; and thereby, through indirect but clear induction, we can fathom the secrets not only of the circulatory apparatus, but of nerve-action and nerve-lesion behind and beyond. And am I to add in this company that the very romance of zoological evolution is brought to enlarge our knowledge of the parasites that infest our bodies, modifying sanitary regulations in a remarkable manner, or that in every practitioner's hand, the microscope and the test tube answer in a moment questions once unanswerable. though on them hang issues of life and death ?

The exploration of the nervous system by electrical agencies, by manometers and the like, through the recent labours of the many, but especially of M. Duchenne de Boulogne, and the registration of changes of temperature in evidence of chemical alterations and in proof of corresponding alterations in the organism, should be cited as among the less developed but equally certain advances of physical inquiry as applied to disease. The framework of medicine simply considered as an art now eepends on accurate data, on experiment, on observation, and direct induction therefrom. But though this be true, yet medicine as an art cannot always go hand in hand with medicine as a science. The physician, with emergencies constantly before him, cannot wait to act till science has established her conclusions with absolute certainty. In so far as medicine is purely scientific it is not in harmony with the average mind of mankind ; in so far as it is empirical it is at variance with pure science. Science being organised knowledge, and admitting no uncertain element, objects to the probabilities which guide the master of the art to his conclusions, and lead him to act with a promptitude incomprehensible and appalling to the uninitiated. Just as the scientific navigator, who is furnished (as every navigator ought to be) with the instincts of the empirical seaman, trusts those instincts in a gale as readily as his accurate observations in clear weather ; so the true clinical physician decides first, and afterwards puts together in logical arrangement the reasons for his decision. In so far as he does this he abandons the order observed in pure science. Still he must do so in many cases if he is to act at all. If he cannot do so, he is apt to become first sceptical, then indifferent. That such scepticism and such indifference may be a real danger in the practice of medicine, and is some counterpoise to the many advantages which modern medicine may derive from her scientific character, is hardly to be doubted. This subject of medical scepticism is too grave to be here passed over without some consideration. Healthy criticism of existing belief is one thing ; mere destructive criticism, with no honest purpose of getting at the truth, is another. The former is a necessary quality in a man of full power ; the latter is the frequent sign of idleness in youth, and of carelessness in advanced years. There was a time when the priest and the physician were one, and when the art of healing was looked on as a supernatural gift. It is so esteemed even now among savages. Cures wrought by a higher intelligence, being above the conception of the "rude untutored mind," seem emanations from the attributes " of the unknown god." The impostor priest could be also impostor physician. Trading on the weaknesses of his fellow-men, he would dogmatise on the ailments of the body and their cure, as well as on the diseases of the mind and their remedies The destruction of such dogmas, groundless though they may be, is a slow and dangerous process, as all students of history can tell. But the time is come when every opinion and conclusion has to be sifted ; and another danger has come rapidly upon us—that of reckless negation of the accumulated experience of our race. What are our fathers to us ? Are we not better than they ? This is with some the modern version of the well-known lamentation :—

> " Ætas parentum pejor avis tulit
> Nos nequiores, mox daturos
> Progeniem vitiosiorem."

But still in the traditions of the past there is a mass of practical wisdom. Nothing is more admirable than the caution and care—the generally scientific spirit, and often the truly scientific method, with which the best men, such as Morgagni, Sydenham, and Hunter, observed and reasoned. It is conceivable that this caution was due in great measure to the uncertainty of the ground they trod, and the want of precision in the means they possessed. We are superior to our fathers in the means at our disposal, and in the positiveness with which we can up to certain points enunciate our results. But we ought not to overlook the fact, that with these positive gains we are subject to contingent losses, and that in an epoch of details and comparatively facile methods of inquiry the great qualities of patience and reserve may be lost to those who are not themselves original investigators. From the causes of twining in the delicate tendril to the causes of variation in the human species, from the causes and local conditions of atmospheric changes to the causes and physical consequences of the combustion of a fixed star, the biologists and physicists of the day are seeking a true cause; and, each in his way appreciated by hundreds of fellow-workers and ten thousands of more or less intelligent followers, is making a step towards the first cause which, Newton says, "Is certainly not mechanical." And what have they reached? First, the conviction, clearly expressed many years ago, of the exquisite interdependence between our entire fauna and flora in the chemical circulation of matter on our globe; and next, the generalisation at once so simple, so overwhelming, that all action of which we are immediately cognisant is but the result of the operation of solar heat upon and through interdependent and correlative existences; that all things in this system are capable only of interchange; that there is no destruction of what exists; no creation of new energy. The theorem of the conservation of energy has not, as may be supposed, brought direct fruit to medicine, but indirectly it has already told in more ways than one. But it explains nothing whatever of the origin of things; nothing of the nature of will. However true it may be that the solar energy was stored up myriads of ages ago in the coalfields, however true it may be that, in the processes of vegetable life and decay, the sun's energy is constantly being first captured and then liberated for further use in other organisms, yet nothing of this emits the smallest spark of information on the *true cause* of orginisation, or of the working of a single organic cell. These fundamental ideas seem at first sight to belong so little to the work of everyday life or to the practice of an art, as hardly to have any relation to them. Yet very little reflection shows how the profession, which has always assiduously pursued, indeed has been the chief promoter of, natural knowledge, cannot separate itself from the indirect, any more than from the direct influence of science, and so has to follow these apparently remote speculations. Who would suppose that the question of spontaneous generation so keenly debated from a very early period to our own year and day, need have any immediate bearing on practice? Yet see how the observations of Pasteur are connected with the questions of infection—nay, more, of suppuration, and (as shown to be proable by Professor Lister) of surgical treatment. It would indeed be a great point if we could prove that no germs, carriers of disease, spontaneously originate, but must always immediately come from a progenitor cell. If so, there would just be a hope that some diseases might be effectually and finally stamped out. What we do know of zymotic diseases does not favour this expectation. At the same time it has to be borne in mind that both the success and the failure of vaccination disclose the existence of properties which it would have been fantastic to expect, but which experiments proved to exist. What the powers of "nature" are in producing and regulating morbid products, and what the powers of man may be, is becoming every day more apparent in such inquiries as those on the relations of vaccination to syphilis, which are now being discussed by Ballard and Seaton. If we take them into consideration, together with the researches into the origin of tubercle by Villemin, Sanderson, and Wilson Fox, the inquiries into the origin of the cattle plague, and the whole state of our knowledge of the nature of what is called infection, we have presented to us certainly one of the most remarkable series of biological and paththological investigations that has been ever recorded, and to an intelligent and cultivated person unacquainted with the state of human knowledge in respect of bialogy, one which must, at first, seem almost incredible. "There are two methods by which the art must work: first, the method of pure science, with no other object but the attainment of knowledge and truth, the method which works by observation and experiment, in physics, chemistry, anatomy, and physiology, by the study of agents, and, where necessary, by vivisections; and secondly, the empirical method, or the method which attempts to cure by rules derived from tradition, probability and tentative experiment."

Now, by the first of these methods we are able to ascertain the law or course of action of the most complicated vital processes, as appears from the researches into tubercle and syphilis to which I but now allude. But this method is unable to explain the relations of phænomena in any, even the simplest organism, for it cannot be said that we at present understand the simplest vital process. Still it is a great thing to see the laws or course of action of living bodies being gradually developed and laid down. We know, for instance, that a certain disease will run a certain course in a certain family. What is this but the law that living matter acts in a definite manner under definite conditions, and that when we can predicate the conditions we can predict some at least of the results? This law is of course the scientific basis of all curative medicine in individual instances, and of all preventative or state medicine in communities. The application of this law to vital as well as to inorganic phænomena strikes a blow at many ancient prejudices which assumed and sometimes fostered the notion of exceptional and erratic procedures, that is to say, of procedures for which no reason could be given. Viewed calmly, it is the ground for all hope of future progress in Therapeutics; and for this reason among others. In the present state of knowledge we are always on the verge of the most amazing results, and we do not know when or where the outcome will be. And slowly, but surely, the siege of the fortress of knowledge advances. Latterly it has shown sign of progress in a new and unexpected direction. Chemistry which used to be chiefly analytical has now become enthusiastically synthetical. There are virtually no limits to the substances which can be made. Berthelot makes a calculation of the number of combinations with acids of certain alcohols. He says if you gave each a name, allowing a line for the name, then printed 100 lines in a page, and made volumes of 1000 pages, and placed a million volumes in a library, you would need 14,000 libraries for your catalogue. He therefore properly calls such bodies infinite, instancing the synthetical construction of the alcohol and aldehyde series, of the organic acids, of the amides, of urea, and the millions of possible bodies which loom in the future—certain to be made, waiting to be made, the possessors of qualities suspected but unknown. I almost hesitate to observe that bodies of this kind have important relations to the properties of the nervous system in man. Chloroform and the various amides employed by Richardson have made this familiar to all. The beautiful experiments by Bernard upon amygdalin show the question to be still more intricate and vast than Berthelot puts it in the passage already cited. It is manifest, therefore, that the possible agents for affecting the human body are infinite, and the instances which I have partially touched on of the relations of glanders, tubercle, and irritation; of syphilis and vaccination, show what might antecedently have been expected—the equally infinite problems which may be experimentally discussed and solved in the higher animal organism, problems equally affecting the classifications of Pathology and Therapeutics. Of the second, or the Empirical method, to which I but now allude, it is not to the present purpose to speak.

Having said thus much on the relations of Modern Medicine and Modern Science, in the hope of vindicating our profession from one-sided attacks, founded on the notion that it is wanting in scientific precision, I leave this light sketch of a vast subject, in order to consider the present relations of Modern Medicine to Humanity; in other words, its relations to the wants of man in the complex state of modern society. There were great armies before the Christian era; there must have been great crowding in ancient Rome; a careful and detailed sanitary code was imposed on the Jewish people at the time of the Exodus; Rome paid no small attention to sanitary works. But neither permanent populous cities nor sanitary codes were the rule. In our day on the contrary, one of the peculiarities of modern life is shown from statistics to be the tendency to increase of population in great towns: so that in England between 1841 and 1851 there was an increase in the population of towns, of over 100,000 inhabitants, of 23 per cent.; and in the following decennial period, 1851 to 1861, there was, in France, in towns of similar magnitude, taken collectively, an increase of 50 per cent. In our day Preventive and Public Medicine has become a great branch of Medical Science. Imperfectly as yet carried out in this country, it is more fully developed in several Continental countries, and, of late in a noble manner, in the United States. It is here and there carried to great perfection, as in various departments of armies; it has made great progress also in navies and in almost every part of civil life. It will suffice to say that we have some reason to hope that we may see the relations which ought to subsist between this department of the Science of Medicine, and the community at large, investigated systematically by a Royal Commission.

To anticipate the conclusions of such a commission would be no becoming occupation. But this may be confidently expected, that one result would be the elevation of the duties of an officer in State Medicine to that of a recognised profession, as in several special instances it has already become. At present it is not uncommon for a young man to be charged with wasting his powers if he devotes himself to improve the public health. Hereafter, charge of the puclic health must be made as much a matter cf honourable ambition in the body politic, and must become as much an object of special education and training, as the business of any other recognised branch of the civil service. The Government will have to define the duties to be discharged by Public Health Officers or other Officers of Public Medicine, and the General Council of Medical Education will be able to direct the education of those who aspire to the performance of duties so defined. I have not here touched on the problems arising from the condition of great towns. They are become part of the literature—I had almost said the sensational literature—of the day. Long familiar with poverty, and the sorrows and penalties and crimes which hang about it, as well as the brightness and patience which called forth the words 'Blessed be ye poor,' I had not learnt the intricacy of these problems till in the work of the Cubic Space Committee (wherein I joined the most able President of your Council) I found myself set face to face with them, and had to consider what was the significance to the State of a child born in the workhouse of a prostitute, brought up during childhood in the workhouse, cast forth into the purlieus of the city becoming pregnant and returning poisoned with syphilitic sores, at an immature age to bear a syphilitic infant; nor did I see the magnitude of the problems till I found that, not in one instance but in thousands, not in one district but in many, is this process being carried on. Where and how these frightful evils can be stopped is known only to Him who can tell the causes which laid desolate whole kingdoms of Asia, and left us to wonder at the ruins of cities whose very names are unknown. But it rests upon us, more perhaps than on any other class in the community, to see to it that no remedy which can be applied, however partially, is neglected, and that no means by which the comfortable and indifferent public can be roused to appreciate the task before them shall be left unused. Still less do I presume to handle now the relation of physiological and medical knowledge to the habits of some among the higher classes—to the conditions of modern society which overstimulate nervous action, the late haurs, the exhausting effort, the wholly unhealthy existence. This is a subject which needs much tenderness and skill, and longer time than you can spare. But it is a subject on which the advancing knowledge and culture of modern medicine will have not a little to say; and which, it may be hoped, will be so said as to be heard.

There is one other relation of modern medicine which it would be improper to pass by, although it is one which an over-prudent man would instinctively avoid—its relation to spiritual beliefs. The reason why an over-prudent man would avoid all allusion to such beliefs is, that he dreads to entangle himself in the maze of angry controversy which not only surrounds, but almost fills, the ecclesiastical world—controversy, not between creeds permanently opposed, as the creeds of Buddhism, of Islam, and of Christendom, but feuds in the bosom of each separate religious system. The reason why we cannot, if we would, avoid considering our own relation to spiritual beliefs, lies in the two fundamental facts, that we are ourselves men like other men, and that we stand in a closer and more real relation to man, as man, than does any other class of the commonwealth. It has indeed been said, "Ubi tres medici, ibi duo Athei." The recent attacks by the Cardinals in the French Senate on the Faculty of Medicine show that the charge conveyed in this aphorism is not forgotten in France. Signs of the same notion are not wanting in this country. What is the fact? The fact seems to be, that the members of the medical profession are in their lives not less religious than the average of the society in which they live. As a body, they are calm, earnest men, who mingle little, perhaps too little, in the questions of the day, and seldom with violence. Religious enthusiasm is rare with them; fanaticism is generally absent; and, on the whole, it may be said that, as a profession, they stand aloof from religious discussion. Self-interest operates in some degree; usage operates to some extent; but there is a deeper reason for their standing aloof, which religious teachers would do well to lay to heart. There are none who know so much of the reality of man's nature, its phenomena, its conditions, its pains, its privileges. To the physician, the bodily nature is bared in its beauty and in its hideousness, in its formation and growth, and in its decay and dissolution, The physician sees in the body of man the material structure by which alone the known operations of the mind of man are possible in this world, the organs by which alone he can work his earthly work, whether it be the work which he shares in common with the beasts of the field, or the work through which he can enter into conscious relation to his unapproachable Creator: the frame by which, while bound down in an earthly charnel-house, he lifts his eyes and strains his heart with yearning ineffable towards a higher nature, and obeys the upward tending impulses of affections strong unto death, affections so pure and so divine as to lose in the love of others even the consciousness of self. All this, and much more, our profession sees as phenomena.

If these, then, be the relations of medicine to science and to the bodily wants and the mental condition of man, and such the character of the physician, what is to be the preparation for his duties? There is no better answer than this of Strabo:—"The value of a poet is bound up with that of the man. He cannot be a good poet who is not a good man." On which Joseph Henry Green, who quotes the passage, says:—"I anticipate no objection when I state that the process for attaining or approximating to this great moral result constitutes, in its scope or end, *a liberal education.*" What that is, and how to be attained, is held by all thinking men to be one of the problems which our age has to solve, in and for the interests of our country. May not grave mistakes arise herein? At all events, in the present transitional condition of this and other questions of social economy, it were a waste of time for an Association such as ours to undertake the investigation of this difficult subject. But so far may be said, that the object of academical education for *our* profession is *from early life to discipline all the faculties.* It is obvious that the physician should be many-sided: he should be capable of sympathy with every form of good; he should have all his senses, eye, touch, hearing, disciplined to nice precision and exactness both in perception and thought. We may take one instance—the bearing of the so-called Fine Arts on the development of certain qualities of mind. There is a refinement of observation and a tact acquired by the study of masters of music, architecture, painting and sculpture, which add a charm to the life and character of a man, whatever be his profession, such as is hardly attainable in any other way. Not, of course, that I would wish all men to be so educated as if they were to be artists or musicians. Mathematics are valuable to train the mind to habits of accurate thought. The mathematics may be forgotten, may vanish in all their details; but the accuracy and precision given by their study may remain. So the practical dexterity of the eye, and hand, and ear, in drawing and in music may be lost; but the delicate perception of form and colour and the relations of colour, of sound and the relations of sound, and the effect produced upon the mind by the study and cultivation of the arts therewith connected, may remain, and tinge with a higher character the whole nature of the man.

It would be trespassing too much on your good nature to ask you to listen to the proofs that an acquaintance with the mental constitution of man, of those ways of ennobling its impulses, and of that mixed knowledge and discipline, which are called religion, is more especially necessary for our profession. I therefore assume that you generally consider every scheme of preliminary education faulty which does not admit this, and will only state briefly what present circumstances seem to require of caution under that admission. Granted that, for the intellectual training of a medical man, religious discipline and psycological knowledge are required, how are they to be imparted? and of what kind should they be? If those who have investigated the subject were agreed as to the nature and origin of human families; if the unity of our race were conceded; if there were no variations in character dependent on family and inheritance; if there were no questions as to the future state, nor disputes concerning our relation to the Infinite; if no questions had arisen within the pale of Christendom as to the scheme of redemption, nor outside that pale as to the evidence of that Christian faith,—then, indeed, the student preparing for medicine would find some definite course of mental philosophy and religious instruction in all colleges from San Francisco to Calcutta. Till that day of united conviction arrive, we must be content to take some general position that all can accept. Nor is this difficult. All will agree that we must, first, study the phenomena of human nature as now known to us, without regard to the origin of man; and, secondly, study the principles of laws which ought to regulate the will and affections of man for the good of himself and society—in other words, the principles of universal morality. Nothing less than this is necessary for the youth who are to follow our profession; nothing more can we now enforce.

It will be useless to denounce the inquiries which tend to explain the relations between thought and material organisation. That bundle (as it were) of qualities, good and evil, which we call mind, does, as far as we know, require for its manifestation the continuity and integrity of a complex organisation. That organisation varies with the qualities which are exhibited. The mental organisation of animals inferior to man is as various as their bodily structure. In truth, we have as good right to call the bodily organisation the material part made for the action of mind, as the mind the consequence of the bodily organisation.

The President then dwelt on the functions of a University and the connection of the profession with them, and concluded thus:—As your representative I have asked freely for what you seemed to desire, and in your name I thank those who have granted it. In the name of your Oxford friends, and as official head of the ancient and honourable Faculty of Medicine in her University, I heartily welcome you to whatever in the lotus-growing, stagnant depth of the long vacation you may find still living here. You bring your own life, from England, Scotland, and Ireland, from the United States, France, and Germany. Live it among us. And in exchange for our welcome to the banks of the Isis give us your thoughts and your counsels, to the end that we may all return refreshed and strengthened to our common and happy toil.

A vote of thanks to Dr. Stokes, the Ex-President, having been then moved by Dr. Sibson, seconded by Dr. Paget, and replied to, the Secretary proceeded to read the Annual Report, from which the following extracts are made:—

"It is with great pleasure that the Council have again to report a continued and considerable increase in the number of the members of the Association. At the end of the year 1867 the number of members was 3130. During the year 56 have died, 68 have resigned, and 111 have been erased for non-payment of subscriptions. Since the 1st of January of the present year 621 members have been admitted. At this time the total number of members is 3627.

"The Treasurer's Statement shows a considerable increase in the receipts, and a sasisfactory state of the finances of the Association.

"The Sub-Committee, appointed by the Council in 1866 'to consider the mode by which the profession at large may be directly represented in the Medical Council,' was re-appointed during the past year, and a deputation of the Sub-Committee, consisting of Dr. Sibson, Dr. Waters (Chester), Mr. Southam, Dr. Simpson, Mr. Nunneley, and the General Secretary (Mr. Husband being unable to be present), had an interview, on the 30th of June, with the General Medical Council. At that interview the deputation presented a memorial in favour of the direct representation of the profession at large in the Medical Council, and they urged its object by arguments, the force of which appear to your Council to be unimpaired by any of the objections raised in the debate which followed in the Medical Council, as reported in the journals, where a resolution was carried to the effect 'that, under present circumstances, it would not be expedient for the Council to consider the propriety of attempting to obtain a change of constitution.' It would have been gratifying to your Council if the Medical Council instead of passing this resolution, had availed themselves of the opportunity thus presented to them, and had commenced the amendment of the constitution of their own body by a movement from within.

"The Council are deeply impressed with the conviction that the direct representation of the large body of registered practitioners in the General Medical Council is an object of high professional importance, that should be steadily pressed by representations to the Government and to both branches of the legislature. They feel satisfied that they have faithfully interpreted, in this matter, the wishes of the profession, and they are convinced that the efforts of the Association will not be relaxed until this object is attained. They recommend that this object should receive the best attention of the Oxford Meeting, and of the various Branch Meetings throughout the kingdom.

"The Committee on State Medicine, appointed last year in Dublin, commenced its duties before the close of the meeting and has since then, in conjunction with a Committee appointed by the Social Science Association, held several meetings. On the 22nd of May, a large deputation from the British Medical and Social Science Associations was received, by the Duke of Marlborough, the Right Honourable Gathorne Hardy, and the Earl of Devon, at the Privy Council Office, and a Memorial drawn up by the joint Committees, showing the necessity of a better administration of the laws relating to registration, medico-legal inquiries, and the improvement of the public health, was presented. The deputation was assured that the Government would give the subjects brought under their notice the best consideration.

"The Sectional Meetings, held for the first time at Dublin last year, were eminently successful. The want, however, of a section at which papers on State Medicine and Medical Policy could be read and discussed, was much felt. This want has this year been supplied by the formation of a Section on Public Medicine, and the Council anticipate that the meetings of that Section will be of deep interest.

"The Sectional Meetings have assumed so sudden and important a development, that the Committee of Council have appointed a Committee to consider and advise as to their future organisation.

"Two essays were received for the Hastings Medal, but your Council regret to announce that the adjudicators—Professor Stokes, of Dublin, Dr. Paget, of Cambridge, and Professor Gairdner, of Glasgow—have reported that they do not consider either of them to possess sufficient merit; and they therefore advise the Medal to be withheld for this year.

"The subject for competition for 1869 is 'Resection of Joints.'"

The motion for the adoption of the Report gave rise to a great deal of discussion, and speeches were made by Mr. Gamgee and others condemnatory of the action of the Council of the Association in regard to their deputation to the Medical Council.

This discussion was revived with considerable energy in a motion of thanks to the Committee.

Eventually an amendment was carried, and after some routine business the meeting adjourned.

Wednesday, August 5th.

The Association met this morning at breakfast, at the Corn Exchange, and the assembly numbered nearly 400. A large number of those present adjourned to the Convocation House at half-past ten, to be present at the granting of honorary degrees to Sir Charles Locock, the Rev. Dr. Haughton, Dr. Gull, Mr. Paget, Mr. Syme, and Mr. Simon.

The place of meeting for next year was, on the invitation of Mr. Nunneley and Dr. Husband, of York, fixed at Leeds, where the new Infirmary is expected to be an object of much interest.

Dr. Chadwick was accordingly chosen as President elect.

The following gentlemen were elected Honorary Fellows, in accordance with the new law, on the motion of Dr. Sibson:—Dr. Cookson (Vice-Chancellor), Professor Airey, and Professor Stokes, of Cambridge; Provost and Vice-Provost of Dublin University; Rev. Dr. Carson, of Dublin; Vice-Chancellor of Oxford, Dean of Christ Church, Warden of New College, Principal of St. Mary's Hall, Sir B. Brodie, Professor Phillips, Professor Clifton, Mr. Chapman, M Duchenne, M. Marey, Professor Victor Carus, Professor Gross, representing the United States Medical Association, and Mr. Edwin Chadwick.

The Joint Report on State Medicine of the Committees of the British Medical and Social Science Association having been then presented by Dr. Stewart, Professor Rolleston proceeded to deliver his address on Physiolgy—a disquisition which displayed very great erudition and ability, and was loudly applauded during its delivery.

WEDNESDAY AFTERNOON MEETING.

The members again assembled at two o'clock, when the Rev. Professor Haughton proceeded to read his communication on the "Relation of Food to Work." The delivery of this lengthened essay was received by the audience with the utmost enthusiasm, and listened to with marked interest.

On the termination of Professor Haughton's address, the Sectional Meetings were opened. In the Medical Section the chair was taken by Dr. Stokes, in the absence of Sir W. Jenner, and a communication was read by Dr. B. W. Foster of Birmingham, "On the Use of Ether and Etherised Cod Liver Oil in the treatment of Phthisis."

Professor Rolleston presided in the Section on Physiology, and papers were read by Mr. Paget "On Stammering with other Organs than those of Speech," and by Dr. Robert McDonnell, of Dublin, "On the relative claims of Bell and Majendie to the discovery of the function of the roots of the Spinal Nerves."

In the Surgical Department Mr. Paget assumed the chair, and heard essays, from Mr. Birkett "On the mortality from Abdominal Hernia," and from Mr. Southam "On the results of Operations for Lithotomy at the Manchester Royal Infirmary."

THE PRESIDENT'S SOIREE.

At half-past eight, the New University Museum was thrown open to a very large assemblage of the members. The tables were covered with a variety of interesting specimens. Dr. Beale exhibited a very complete series of microscopic preparations in Anatomy and Physiology. The Sphygmograph and Cardiograph were demonstrated in an adjoining room, and a variety of novel scientific instruments were exhibited and explained by Professor Clinton.

THURSDAY THE 6TH.

The Fourth General Meeting was held at ten o'clock, and the report of the Committee on the action of Mercury on the Biliary Secretion, was presented by Dr. Hughes Bennett. The experiments had been principally conducted on dogs, and their result is very startling as tending to overthrow all hitherto received ideas in the matter. The ultimate conclusion arrived at is that, inasmuch as mercury is found to act in most respects on dogs exactly as it does on the human subject, its effect on the secretion of bile may be assumed to be similar. That, nevertheless, it is found in moderate doses not to stimulate that secretion, and in large doses to act in the direction of retarding it.

The Report of the Parliamentary Committee was then read, and a Committee was appointed to confer with the Council of the Poor-law Medical Association.

The Sectional proceedings this day were signalised by a very able paper on "Preventive Medicine," read by Mr. Simon, in the Public Health Section.

The Public Dinner of the Association took plaee in the evening in the Hall of Christ Church.

Correspondence.

LETTERS ON MEDICAL REFORM.—No. II.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The great importance of some of the "higher questions" which must necessarily occupy the attention of our representatives on the Medical Council, when the profession shall have acquired the right of self-government, renders it desirable that professional men should think over and make up their minds upon them before they are called on to name the conditions on which they will support such and such candidates for the honour of representing them and upholding their interests on the Council.

One of the first and most important of these questions is that of preliminary education. What are its objects? what ought to be its nature and scope? and whether a high standard or a low standard ought to be maintained? To which latter question, if put in a general way, I presume no person could think of replying that the standard ought to be low, though the vital importance to us, both as a body and as individuals, of maintaining a high standard, may, perhaps, be worth demonstrating. The object of the preliminary examination is of course to test intellectual ability in general, and in particular the possession of such special qualities and faculties of mind as shall guarantee that a young man shall be able to study and practise medicine with satisfaction to himself and benefit to the public; such powers of mind as shall ensure that after four years of average work, he shall be able without fail to pass his professional examination, and shall not find himself compelled, after so many of the best years of his life shall have been spent in the study of medicine, either to turn to some wholly different pursuit, or to settle down, as is so often done in England, as an unqualified assistant or practitioner, with just enough knowledge to be able to pass himself off as being very learned among the lower middle classes, underselling the respectable practitioner, and lowering the general estimate of medicine as a science, and medical practice as a pursuit. It is, indeed, of the utmost importance to us that a somewhat higher standard even than this shall be reached, since every additional member added to the profession increases the number of candidates for practice, and so far lowers the standard of professional remuneration; and this more especially when the new member is a man of low attainments, and hence under the influence of very strong pressure to undersell his brethren for the sake of his own livelihood. I know what the answer to this line of argument will be in the minds of a very large number of medical men. They will say—"It is very true that a high standard of preliminary and professional requirements will benefit us individually, but we have sons to put into the profession, and whom we hope to succeed us in our practices, and if we raise the standard of either examination too high they will not be able to enter the profession."

I presume that the difficulty is not one of cost, for which of us would not be willing to spend a little more on his son's education, and it would be but very little more, in order to get him into a profession so much better paid under those conditions than it is at present; but the question is one of intellectual ability to pass the higher examinations. Undoubtedly there would be some lads found, sons of medical men, who could not pass the barriers when raised, but these would obviously fail in the practice of their profession if they should now succeed in passing, and would do much better by selecting some pursuit in life requiring less study, thought, and grasp of mind. But I wish to urge it strongly on my medical brethren, that except in such rare cases the raising of the barriers is a movement altogether in favour of their sons as against others. Those who would be kept out by such a change would be the sons of the petty farmer and shopkeeper, who now look upon the profession as affording them an entrance into the rank of gentlemen. This will be obvious, on a little consideration, by a comparison of the relative advantages possessed by the son of the medical man over the son of a farmer or shopkeeper, as regards the passing of the preliminary and professional examinations.

The son of the medical man is brought up from his infancy in what we may call a scientific atmosphere. The knowledge which his father possesses of chemistry, natural philosophy, botany, and, we may almost certainly add, of mathematics and classics, is unquestionably very great when compared with that of the farmer or shopkeeper. In the company and through the conversation of his father, these things ingrain themselves into the lad's mind; they are the foundation upon which his education is built, the frame-work around which his ideas twine themselves. His rival meanwhile thinking on crops, the flocks and herds, or the markets, stores, and stock in trade, if indeed he ever *think* at all, in the sense in which a medical man understands the term. Which of these two lads will best and most thoroughly take up the instruction necessary for a high preliminary examination; on the side of which will the advantage lie in passing the examination, if the barriers be only raised high enough?

But this is an absolutely necessary step if the advantage is to be thrown where it really lies, on the side of the medical man's son; for, to illustrate the point by a reference to athletic sports, what advantage would the active and well-trained hurdle-leaper have over the clod-hopper in a race where the hurdles should be only one foot high?

I must defer to a future occasion the further consideration of this subject.—I am, dear sir, yours faithfully,

ISAAC ASHE, M.B. T.C.D.

Medical News.

THE PUBLIC HEALTH.—We extract the following from the weekly return of the Registrar-General :—In the week that ended on Saturday, August 1, 4416 births and 3770 deaths were registered in London and in 13 other large towns of the United Kingdom. The annual rate of mortality was 31 per 1000 persons living. The annual rate of mortality last week was 28 per 1000 in London, 25 in Edinburgh, and 23 in Dublin; 25 in Bristol, 39 in Birmingham, 36 in Liverpool, 36 in Manchester, 39 in Salford, 38 in Sheffield, 39 in Bradford, 39 in Leeds, 36 in Hull, 26 in Newcastle-upon-Tyne, and 30 in Glasgow. The rate in Vienna was 35 per 1000 during the week ending the 25th ult., when the mean temperature was 5·1 deg. Fahrenheit higher than in the same week in London where the rate was 31. The mortality from diarrhœa showed a decline last week in London, but had further increased in several of the other large towns, especially in Birmingham and Liverpool. The annual death-rate from this disease during last week was 4 per 1000 in Newcastle-upon-Tyne, 5 in Bristol, 6 in London, 9 in Bradford, 10 in Manchester and Hull, 11 in Liverpool, 12 in Salford, 13 in Sheffield, 14 in Leeds, and so high as 20 per 1000 in Birmingham. There is little doubt that under a well-organised system for treating the disease in its earlier stages this mortality would rapidly decrease, and the risk of the more dangerous choleraic forms would be reduced to a minimum. The deaths of 859 males and 806 females, in all 1665 persons, were registered in London during the week. It was the 31st week of the year; and the average number of deaths for that week is, with a correction for increase of population, 1583. The deaths in the present return exceed by 82 the estimated amount, but are less by 220 than the number recorded in the preceding week. The deaths from zymotic diseases were 691, the corrected average number being 638. Five deaths from small-pox, 46 from measles, 47 from scarlatina, 9 from diphtheria, 32 from whooping-cough, and 52 from fever were registered. Thirty-eight deaths from choleraic diarrhœa or cholera were recorded ; 27 fatal cases were those of children under two years of age ; five children who died were aged from 2 to 10 years, and 6 fatal cases occurred in adults. 384 persons died from diarrhœa ; of that number 42 were adults. The mortality from diarrhœa and choleraic diarrhœa or cholera in the London waterfields to 100,000 living was 12 in the New River, 11 in the Grand Junction, 17 in the Southwark and Lambeth, 14 in the East London, and 18 in the Kent fields of supply. The deaths of 6 persons from sunstroke were recorded ; and in many cases the fatal termination of diseases was stated to have been accelerated by the great heat. At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·801 in. The barometrical reading increased from 29·51 in. on Tuesday, July 28, to 30·16 in. on Saturday, August 1. The mean temperature of the air in the week was 67·6 deg., which is 5·3 deg. above the average of the same week in 50 years (as determined by Mr. Glaisher). The highest day temperature was 90·1 deg., on Tuesday, July 28. The lowest night temperature was 49·4 deg., on Saturday, August 1. The entire range of temperature in the week was, therefore, 40·7 deg. The highest reading of the thermometer in the sun was 167·0 deg. on July 28. The mean of the highest temperatures of the water of the Thames was 68·7 deg.; that of the lowest was 68·4 deg. The difference between the mean dew point temperature and air temperature was 12·9 deg. The mean degree of humidity of the air was 64, complete saturation being represented by 100. Rain fell to the amount of 0·23 in. The general direction of the wind was W.S.W. and S.S.W. Ozone was observed on five days during the week. According to a return furnished by the engineer of the Metropolitan Board of Works, the daily average quantity of sewage pumped into the River Thames at the Southern Outfall Works, Crossness, was 46,190,315 gallons, or 209,864 cubic metres, equivalent to about as many tons by weight.

MALVERN COLLEGE.—The annual speech-day was held on the 28th ultimo., and the Scholarship Examinations closed on the 30th. After a few introductory remarks by the head-master. The Rev. Arthur Faber, M.A., announcing the increase of the school, &c. The usual speeches were delivered by the pupils with much spirit, receiving at the conclusion loud and well merited applause. The prizes were then distributed, the chief award being the Beauchamp prizes (classical), J. Haworth, E. N. Jones, H. Barnes ; the Gully prizes (modern langauges), J. Smith, S. Curtis, A. Robinson, H. Walker ; the Council prizes to R. M. Drew, D. Faber, J. Perks, A. Hill, F. Pottes, J. Scholfield ; Modern department prizes to J. Rogers, J, Staight, &c. The Scholarship Examinations were concluded on the 30th. The Bishop Philpott Scholarship was awarded to H. Barnes ; the Council Exhibition to R. M. Drew and C. Lushington ; and the Modern Exhibition to H. Bowen.

BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The stated quarterly meeting of the committee of this local branch of the above invaluable society was held on Wednesday, 5th August, at No. 33, High-street. James Moore, Esq., M.D., M.R.I.A., was called to the chair. Amongst the other members present were:—Dr. Patterson, Dr. Whittaker, Dr. Wilberforce Arnold, and the honorary secretary, Dr. Stewart. The minutes of last meeting were read and confirmed. It was now reported that the several parties, six in number, who had been recommended for grants at the annual meeting of the Parent Society held in Dublin in June last, had since received the several sums, as had been suggested, and for which each was deeply grateful for the timely assistance so rendered. The only regret felt by the Parent Society was that more liberal grants could not be awarded, the total sum in hands being so very limited. It was pointedly observed at the meeting to-day how comparatively few of the profession in Belfast gave any pecuniary aid or countenance whatever to a society which, for its means, was doing so much good, and whose objects were so purely disinterested and humane. Much conversation took place as to the best means to be adopted to increase the number of the actual subscribers to this branch, especially in respect of Belfast, in which the names of little more than a third of the practising members of the profession were in the list of subscribers. Amongst other resources approved of to increase the list of subscribers, it was unanimously decided upon that it be an instruction to each member of the committee, in town and country, to use his influence as far as possible in furtherance of so good a cause as the society was engaged in, by making more widely known its really humane objects, and soliciting on its behalf the aid of every member of the profession, as well as of the affluent not belonging to its ranks, but upon whom the medical profession had the strongest claims. A letter was read from the Secretaries of the Parent Society requesting that the subscriptions of the respective branches would be transmitted to the Treasurer, in Dublin, as early in the month of May, yearly, as possible, a request which it was resolved should be acted upon for the future by this branch. After transacting the usual routine business the chair was vacated, and the meeting separated.

STATISTICS OF INSANITY IN IRELAND.—By the aid of the Royal Irish Constabularly and the police, a very careful inquiry has been recently made throughout Ireland into the number of insane persons not placed in any asylum or other institution (including wandering lunatics), with a view to ascertain by the returns, coupled with those from asylums and other establishments, the gross amount of insanity in the country. The result is as follows :—On the 31st of December, 1867, there were 5212 insane persons in public asylums in Ireland, and 626 in private asylums ; 2705 in poor-houses; 334 in goals; 158 in the Dundrum central asylum for criminal lunatics, and 51 in Lucan private asylum, supported by the Government ; making 9086 registered lunatics. To these are to be added 6564 lunatics at large, making the total number of the insane in Ireland, 15,650. In Connaught they constitute 2·0 per 1000 of the population enumerated at the Census of 1861 ; in Ulster. 2·4 per thousand ; in Munster, 2·7 per thousand ; in Leinster, 3·0 per thousand. Taking Ireland as a whole, the number is 2·7 per thousand of the population at the Census of 1861, or 2·8 per thousand of the estimated population at the end of 1867. All classes of persons of unsound mind are included —lunatics, idiots, epileptic imbeciles. Omitting the 51 in Lucan not classified, 8322 are males, and 7277 females. The returns relating to the 5212 patients in district asylums show that in 952 cases the insanity was due to moral causes; in 1074 to physical causes; in 542 it was hereditary; in 2644 the cause was unknown. An examination of the 952 cases of insanity traced to moral causes shows that in 280 cases it arose from grief, fear, or anxiety ; in 190 from poverty and reverse of fortune; in 154 (57 men and 97 women) from love, jealously, or seduction; in 93 from domestic quarrels and afflictions; in 129 (53 males, 76 females) from religious excitement; in 59 from study and mental excitement; in 30 from ill-treatment; in 9 from pride; in 8 from anger. Among the 1074 cases of insanity from physical causes are 289 from intemperance and irregularity of life, 76 from effect of climate or sunstroke, 14 from abuse of medicine, 30 from sedentary habits. There were 5070 patients in district asylums at the beginning of 1867, and 1527 were admitted in the year, making 6597 under treatment; 638 were discharged recovered in the year, and 465 dead. More than one-fourth of the lunatics in these asylums (excluding idiots and epileptics) were pronounced probably curable.

THE COCKCHAFER.—M. Payen communicated to the Academy of Sciences the leading points of a paper published in the "Mémoires" of the Société d'Emulation of Abbeville, by its vice-president, M. E. Hecquet d'Orval, on the enormous havoc caused in 1866 by the white grub, or larva of the cockchafer. In Lower Picardy the damage done to breadstuffs amounted to from 35 to 50 per cent., to fodder and meadows to between 25 to 50 per cent.; to beetroot, potato, and poppy to 50 per cent., while the Jerusalem ortichoke only suffered at the rate of 27 per cent. The average amount of the loss in the aggregate is therefore 40 per cent., chiefly owing to the larva of the cockchafer, but also partly to the *Agrotis segetum* caterpillar. The author of the paper shows that a severe winter fails to destroy any great quantity of these enemies, and that, if moles do some little damage to fields, it is far outweighed by the great services they render agriculture by devouring grubs. He also rejoices to see that birds are more protected now than formerly. Ground lying fallow is generally a hotbed for the propagation of the white grub, and such fields ought, therefore to be ploughed and harrowed at least five times during the year, when these worms are near the surface; in that way they are either picked up by the birds or killed by the heat of the sun. M. Payen remarked that last year M. Reiset proved that the collecting of these noxious insects may be effected on a large scale at a very moderate cost; they might then be easily killed by the vapours of napthaline, and used for manure. In the department of the Oise, M. Lallouette, proprietor of the sugar manufactory of Barberie, last spring paid 20f. for every 100 kilog. of cockchafers, and for 6000f. obtained 30,000 kilog. of them, representing 34 millions and a-half of individual insects, which would have produced 690 millions of white grubs. The department of the Seine Inférieure, last year, at a cost of 80,000f., got 1,149,000.000 cockchafers, which might have produced 22,980,000.000 of white grubs, capable of devouring the produce of 300,000 hectares (750,000 acres).—*Galignani.*

◆

OBITUARY NOTICES.

THE LATE DR. ELLIOTSON, F.R.C.P. AND F.R.S.—This distinguished member of the medical profession, who died, at the advanced age of 82, on the 29th ult., whilst staying at the house of an old and attached friend, our contemporary, the *Standard*, says, was the son of a chemist in the borough, in which the subject of the present short notice afterwards practised. As soon as his preliminary studies were completed he went to Edinburgh, then the chief medical school in the kingdom, At Edinburgh he remained three years, and proceeded to Cambridge, where he graduated, and took his degree of M.D. In 1817 he became assistant-physician to St. Thomas's Hospital, and a few years later one of the principal physicians. On the establishment of University College, in Gower-street, he was appointed Professor of Medicine in that institution and physician to the hospital. These offices he resigned in 1838 in consequence of the opposition raised to his system of mesmeric treatment of cases in that hospital. Before Dr. Elliotson yielded his faith to the marvels of mesmerism he made some useful contributions to medical literature; among which he published a translation of "Blumembach's Physiology," and a work on "Diseases of the Heart." He had a very extensive practice, and was the first man to introduce the use of the stethescope into this country. He was elected a Fellow of the Royal College of Physicians in 1822; of the Royal Society, in 1824; and has been president of the Royal Medical and Chirurgical Society.

THE LATE DR. STEVENS.—It becomes our duty to record in this week's *Herald* the death of a gentleman who made for himself a name not only in this locality, where he was well-known, but in the wide world of science also; we allude to William Stevens, M.D., D.C.L., formerly of the Island of St. Croix and of this city. Dr. Stevens was a very eminent physiologist, and recognised as a man of exceptional acquirements by the ablest men of his day. In 1834 he was chosen by the University of Oxford, on the inauguration as Chancellor of the Duke of Wellington, as one of the three members of the medical profession to whom the honorary degree of D.C.L. was awarded in convocation, the other members of the triumvirate being J. H. Hume, M.D., and Sir Astley Cooper, M.D. The magistrates of the county of Middlesex awarded Dr. Stevens a vote of thanks and presented him with a piece of plate of the value of a hundred guineas as an expression of gratitude for his valuable services in combating the cholera in the county prison of Coldbath Fields, and King Christian VIII. of Denmark, in admiration of his genius, and in requital of his valuable services rendered in the Danish West Indies bestowed upon him a princely gift. The mode of treatment adopted by Dr. Stevens in cases of cholera is now acknowledged to have been founded upon a most enlightened view of the diagnosis of that terrible disease. His writings upon diseases of the blood will always be recognised by the profession, and he leaves a monument of his research in the well-known remedy for all affections of the kind, sold everywhere as "Lamplough's Pyretic Saline." Dr. Stevens had reached the patriarchal age of 82. A genius, a philosopher, and a man of strong and original thought, he lived down prejudices, and had the pleasure of seeing his theories carried into practice by men who were at one time a little too willing to cry him down.—*Worcester Herald.*

19TH July, on board the African Mail-boat, Lagos, on his passage home from Sierra Leone, John Bradshaw, Esq., L.K.Q.C.P.I., and L.R.C.S.I., Staff-Surgeon, aged 32 years, fourth son of the late Dr. George Bradshaw, of Thurles, county Tipperary.

Dr. Bradshaw fully maintained the prestige of the Dublin Schools of Medicine, as by his superior attainments he was promoted to the rank of surgeon after serving only four years and three months as assistant-surgeon.

He was a young man of much promise as regards his profession, and had endeared himself to all who had the pleasure of his acquaintance by his many sterling good qualities.

NOTICES TO CORRESPONDENTS.

Proofs reaching authors in England on or before Friday morning are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper only.

All Communications and Letters must be authenticated by the name of the writer, though not necessarily for publication.

J. M. J.—Having perused the *memorandum* in question, we do not think it would be sufficiently interesting to our readers, to accord it space in our columns. We are disposed to question whether the flesh of the Kangaroo, is the article, *par excellence*, for assisting the digestion of all other foods.

A SUBSCRIBER.—Your friend in Washington, should have no difficulty in procuring the regular supply of this journal, if his commands were given to Messrs. Kelly and Piet, Baltimore, who are our sole agents for the United States.

Dr. E. S.—Mr. Walton, of Gower-street, is the publisher of the book in question, we believe the price is 3s. 6d.

◆

APPOINTMENT.

EDWARD BOROUGH, M.R.C.S., L.R.C.P.E., late Senior Assistant House-Surgeon to the Leeds Dispensary, has been appointed House-Surgeon to the Leeds Fever Hospital, vice Henry C. Libbey, Esq., resigned.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (King's Coll.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

TO PHYSICIANS.—There is a capital opening for a qualified M.D., in a borough town, in the Midland district. Population about 4500. The neighbourhood is extensive and respectable, and there is no resident Physician within about 12 miles. Until within the last three years a good fee-practice has been carried on above 40 years. A middle-aged gentlemen, with a small independency, would find this a desirable opportunity. Address X 350, Mr. Langley, as above.

JUNIOR PARTNERSHIP.—There is a vacancy in a large town in the North of England for a Junior Partner, to conduct a Branch Practice, which has been carried on for 11 years. Receipts £400 a-year; considerable scope for increase. The whole connection can be transferred. Address X 349, Mr. Langley, as above.

DENTAL.—In the West of England the incumbent of a well-established Dental Practice is willing to retire, and transfer his connection to a well-qualified successor. Receipts £370 a-year. House in excellent situation, at a moderate rent. Furniture, instruments, &c., optional. Address X 348, Mr. Langley, as above.

SEA-SIDE, S.—A gentleman in large practice in an improving watering-place, is about to devote himself to a speciality, and is willing to introduce a doubly qualified gentleman to his General Practice, by partnership arrangement. About £450 a-year may be at once secured. Address X 347, Mr. Langley, as above.

MIDLAND.—In a large and wealthy town, a Practice for transfer, with one year's Partnership introduction. Receipts £600 a-year, capable of large increase. The residence is situated in a main thoroughfare, and is very commodious, with Garden and Stabling; Rent £65. No Dispensing. Midwifery Fees from £1, 1s. upwards. All appointments have been declined. This investment can be confidently recommended to an active married gentleman with good qualifications and address. Address, X. 344, Mr. Langley as above.

PARTNERSHIP.—For Transfer, the Half-share of a large Practice, the income from which is upwards of £800 a-year, derived from public appointments. The opening affords an unusually good opportunity for a young unmarried man, who could succeed to the whole Practice at the end of two years. A knowledge of the Welsh language is desirable, but not indispensable. Address X. 341, Mr. Langley, as above.

COMPETENT ASSISTANTS Provided without delay, free of expense to the principal. No gentleman recommended whose antecedents have not been inquired into. Apply to Mr. Langley as above.

LOCUM TENENS can be despatched by an early train after receipt of letter or telegram stating terms, duties, and qualifications required. Fee 10s. 6d. Address Mr. Langley as above.

Now ready. Second Edition, with considerable additions.

ADVICE on Buying or Selling Medical Practices, Partnerships, &c. By J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. Free by post for seven stamps, from the Author, 50, Lincoln's-Inn-Fields.

QUEEN'S COLLEGE, CORK.

SESSION—1868-69.

MATRICULATION AND SCHOLARSHIP EXAMINATIONS.

ON TUESDAY, the 20th of OCTOBER next, will be held in the College, an Examination for Matriculation; and for Scholarships on Thursday, the 22nd.

The Council have the power of conferring at these Examinations—Eight Senior Scholarships, of the value of £40 each; and Forty-six Junior Scholarships, varying in value from £20 to £25 each; to Fifteen of which first year's Students are eligible.

For Prospectuses and further information, apply to the Registrar of the College.

Signed by Order of the President,

ROBERT J. KENNY, Registrar.

LONDON NURSES' INSTITUTE,

118, New Bond-street, London, W.

(Removed from 42, South Audley-street.)

TRAINED NURSES (Medical, Surgical, Mental, and Monthly), can at all times be obtained from this Institute.

Hospital Appointments by special arrangement.

Letters and Telegrams should convey the nature of the case to be attended.

Apply to the Manager or Matron. T. HAMILTON, Manager.

THE LONDON SURGICAL HOME,

FOR Diseases and Accidents of Women; for the Reception of Gentlewomen and Females of respectability, upon a weekly payment, under the sole management of Mr. Baker Brown.

The Private Medical Attendants of the patients are invited to visit them, and to meet in consultation before treatment.

Full particulars can be obtained on application to the Lady Superintendent, 18, Stanley-terrace, Notting-hill, London, W.; or to Mr. Baker Brown, 136, Harley-street, London, W.

30th November, 1867.

TO APOTHECARIES AND SURGEONS.

FOR DISPOSAL, in one of the best business towns in the South of Ireland, a Medical Hall, established over 50 years, with a splendid Retail Dispensing and Prescribing Practice. Receipts at present, £400 to £500 a-year, but capable of great extension under an energetic man. Shop at present contains a large stock. Rent only £30 a-year. Apply to M. K., Post-office, Thurles.

TO BEGINNERS.

FOR Transfer, a practice in one of the pleasantest localities in the north of Ireland; appointments exceed £100 per annum; patients include the best residents in the locality. Considerable scope for increase. Very comfortable residence, with every convenience, on lease at a low rent. Further particulars on application by letter, to M.D. Practice, Post-Office, Rathmines, Co. Dublin.

IN consequence of the intended retirement of a medical gentleman from an old and valuable Practice, a peculiarly advantageous opportunity is afforded for a successor possessing first-rate qualifications.

Address M.D., Medical Press and Circular Office, 3, Lincoln-place, Dublin.

THE MEDICAL PROFESSION.

THE ALBERT LIFE ASSURANCE COMPANY. Established 1838—Annual Income £350,000, accepting healthy and invalid lives, is prepared to enter into special and liberal arrangements with members of the Medical Profession acting as private Agents of the Company.—Apply to the Secretary, FRANK EASUM, at the Chief Office, 7 Waterloo-place, Pall-Mall, London.

SIX POUNDS PER WEEK

while laid up by injury, and

£1000 IN CASE OF DEATH

caused by accident of any kind,

May be secured by an annual payment of from £3 to £6, 5s.

TO THE

RAILWAY PASSENGERS ASSURANCE COMPANY,

For particulars apply to the Clerks at the Railway Stations, to the Local Agents, or at the offices,

64, CORNHILL, and 10, REGENT-STREET,

W. J. VIAN, Secretary.

ESTABLISHED 1812.

For the Sale of Leeches and all kinds of MEDICAL HERBS. H. POTTERS, Depot, 56, Farringdon-street, London, E.C. His new priced Catalogue sent to any address on application. H. P. has on Sale all kinds of Turkey and Honey-Comb Sponges.

The Medical Press & Circular.

ON THE NERVOUS CONNECTION OF CERTAIN SKIN DISEASES.

By HENRY SAMUEL PURDON, M.D.,

PHYSICIAN, BELFAST DISPENSARY FOR DISEASES OF THE SKIN, ETC.

In a former paper[1] I endeavoured to point out one or two symptoms held in common in three distinct diseases—viz., Herpes, Pemphigus, and Urticaria. Since the publication of that paper an interesting article has appeared, by Dr. Handfield Jones, on "Pleurodynia accompanied by a Peculiar Eruption."[2] Drs. Woakes, Morris, Wilson, &c., have also contributed papers on the nervous origin of many skin diseases.

The nervous system is divided into two orders—viz., the cerebro-spinal and sympathetic; the former comprising the brain and spinal cord, together with the nerves proceeding from those structures; the latter presides over organic life. Its nerves being chiefly sent to the blood-vessels, glands, and internal viscera, intimate communication exists between the two systems; but, as our enquiry is more towards the nervous relations of various cutaneous diseases, I shall only state that the skin which envelopes our bodies is of varying thickness in different regions. No nerves or blood-vessels have as yet been traced into the epidermis, its nutrition being carried on by means of the selective properties of the cells; and upon the deep or under surface of the cuticle granular cells are abundantly found. The tactille papillary layer of the cutis vera presents furrows which pursue different directions, separated by elevations which are occasioned by a double row of conical papillæ, and into which a couple of capillary loops, together with a nervous twig, enter. The skin is united by "connective tissue," which is loose and soft in texture, to the subjacent parts, and which allows of motion taking place. Into this connective tissue an exudation may take place, especially if the part be very vascular. Nerve irritation may occasion an exudation, which is due to direct transudation from the capillary vessels themselves; for, according to Bernard and other physiologists, the cerebro-spinal nerves cause dilatation of the capillaries, the sympathetic, the opposite—viz., constriction; and if these two functions be not equally balanced transudation may take place; or, according to Dr. Woakes,[1] "the capillaries are in a state of equilibrium between the forces exercised upon them by these two portions of the nervous system. A state of tone is in this way maintained in them, the greater in accomplishing which is referable to the regulating influence of the sympathetic fibres. By the term 'tone' is meant that condition of equilibrium between the capillaries and tissue cells surrounding them which is necessary for the exercise of those elective functions by the latter, upon the due performance of which the ultimate process of nutrition mainly depends."

When the skin is inflamed, say, for instance, in erythema, we have—when the disease is chronic—an exudation poured forth into the subcutaneous tissue; or papules may appear at certain anatomical points, as, for instance, at the orifice of hairs, gland ducts, or other vascular spots, as is well observed in eczema lichenoides.

Herpes and pemphigus form the connecting link between erythema, on the one hand, and urticaria, on the other. In erythema both the corium and subcutaneous cellular tissue are infiltrated with fluid which many pathologists consider to be exuded through the walls of the capillary vessels; and, according to Virchow,[2] "the exudation that we meet with is essentially composed of that material which is generated by the altered condition of the inflamed part, and of the transuded fluid which escapes from the vessels." In an article on "The Passage of Blood Corpuscles through the Walls of the Vessels," *Medical Times and Gazette*, May 2nd, 1861, the following occurs:—"The second experiment consists in producing congestion of the capillary system in the web of a frog's foot by the application of a ligature to the femoral vein. The resulting phenomena are:—1st, retardation of the stream; 2nd, the occurrence of oscillation; 3rd, stasis. This is followed by massing together of the corpuscles to the walls of the vessels, which usually become pouched at these points. On relieving the congestion, by removing the ligature, the conglomerates of corpuscles break down and the stream recommences. The corpuscles, however, which had become adherent to the walls are now *seen to pass through them* and to appear in the surrounding tissues. They are followed by others, and soon the spaces between the capillary network will become loaded with blood globules. In attempting to determine how this process takes place, we have to consider, first, whether there are really apertures in the vascular parietes; and, secondly, whether the result is due to any peculiar properties of the blood corpuscles themselves. Dr. Cohnheim inclines to the belief that interspaces exist between the cells of the lining membrane of the smallest vessels; and, in this view, he is supported by the fact that openings have been proved to exist in the smaller branches of the lymphatic system, apparently in connection with the stomata-like orifices in the epithelium of the serous membranes." The so-called trophic nerves have allotted to them the office of regulating nutrition, but the vaso-motor nerves fulfil the same function, control the flow of blood and the vital actions of the different parts. Hyperæmia and effusion are common to certain skin diseases, and which are owing to nerve irritation—the transudation to pressure. This latter may be limited or diffused according to the nature of the disease and the tract of nerves injured. In large nerves the vasal filaments may be bound up with the sensory when there will be more pain accompanying the disease, as in herpes. Belladonna has the power of acting on the vaso-motor nerves, causing them to constrict the vessels, and is valuable medicine in herpes, engorgement of the mammary gland, &c.

---

[2] "Cell Pathol.," page 356.

Owing to injury of nerve trunks, a change of structure is observed in the skin, which covers the distribution of the affected nerves, and from the observations of Dr. Woakes[1] and American army surgeons during the late civil war in the United States, on cases of injury to nerves by gunshot wounds, &c., it appears that the skin affected usually takes on either an erythematous, papular (lichen), or herpetic character. It also loses its hair (when on the head alopecia), is smooth and glossy. I have met with a disease of the hair which might be called "fragilatas crinium," or extreme brittleness of the hairs, an affection in which no parasitic fungus could be detected, which is essentially a disease of defective or deficient nutrition and of nervous origin. The following are the brief notes of the case:—J. M., aged 45, consulted me on March 4th, 1868, for a "breaking-short" and brittleness in the hairs of his left whisker, which has existed for about one year. He cannot offer any explanation of how the affection commenced, and never had syphilis. His health latterly has not been good, is very nervous, easily agitated, sleeps badly at night, and troubled with dyspepsia. No parasite could be detected on the hairs, for at first sight it presented some of the appearances of the declining stage of tinea tonsurans, except the brany desquamation of the cuticle, the skin of the affected part being healthy. The hairs were uneven in length, fissured longitudinally, and extremely dry, but of the natural colour, which was black, thus differing from the hairs in tinea tonsurans, which are usually bent, of a lighter colour than natural, nodulated, and easily broken; this latter state being due to the sporules of the "tricophyton tonsurans," which are embedded in their structure. The hair bulbs in "ringworm" are also diseased and considerably enlarged, but in this case were quite healthy. I considered the affection to depend on atrophy of the hair, arising from defective nutrition, which was due to impaired nervous power, and consequently prescribed tonics internally, and locally the application of a stimulating lotion, the hair being kept cut short.

Should another case of the above affection present itself I would be inclined to try phosphoric acid, considering, as I do, that the disease was of nervous origin. The presence of dyspepsia in this case is also of interest, and in Bostock's Physiology, page 92, I found the following passage:—"Vanquelin found that the colouring matter of the hair is destroyed by acids, and suggested that when the hair has suddenly changed its colour, and becomes white in consequence of any mental agitation, it is owing to the production of an acid in the system." But this idea seems to be very hypothetical. No doubt, in the case recorded, dyspepsia, accompanied by acid eructations, was present, and a form of dyspepsia has been called "nervous," usually arising from mental anxiety, but to establish a case between them would be difficult; nor is it at all easy to account for how the physical properties of the hair was changed, except on the ground of nervous origin. But, to return from this digression, M. Dubois-Reymond has examined into the so-called quiescent state of nerves, and found that cell growth depended upon the nature and intensity of the exciting cause, and that nervous depression gives rise to hyperæmia, eventually leading to disease of nutrition; and in the rare disease called morphœa, in which, according to Mr. E. Wilson,[1] "The nerves and the capillary vessels, the papillæ, in fact, the more highly organised of the tissues of the skin have become atrophied. . . . While, therefore, we regard this remarkable disease pathologically as a retrograde metamorphosis of the tissues of the derina, originating in neuro-paresis, as, in fact, a fibrous degeneration of the skin, we must look upon it therapeutically as a debility and aberration of nutritive power." Morphœa, when situated on the head, exhibits a bald patch, of a white appearance, and corresponding to the distribution of particular nerves.

In the disease known as prurigo, we have, on the authority of Dr. Parkes,[2] a highly exalted, sensitive, and irritable condition of the nervous system, a condition not unfrequently depending on a morbid state of the spinal cord; and from the researches of M. Bréschet on the structure of the skin, we are made aware of the fact, that the various nerve filaments proceeding from different trunks are dispersed in many directions, and ramify and subdivide minutely on approaching the cutis, ultimately entering the papillæ. Again in gutta rosacea, a disease due to debility, a close sympathy and nervous connection is evident between the part affected—viz., the sebaceous follicles and the reproductive organs and uterine functions. We have in this disease a determination of blood to the capillary vessels of the diseased part, in fact, a hyperæmia, and which finally ends in suppuration.

Like erythema, herpes and pemphigus are diffuse eruptions, appearing over a considerable extent of surface at once. Pemphigus resembles urticaria, and which, according to Hebra,[3] "not only in its acute, but even in its chronic form, sometimes presents the peculiarity, that instead of wheals, bullæ are found at certain spots. But no one need be astonished at this exceptional occurrence, who bears in mind that wheals themselves result from the pouring out of serum, and that an *increase in the quantity* of fluid is all that is necessary to raise the cuticle over a wheal, and to form a bleb. That this was known to the older authors is proved by the expressions *urticaria vesiculosa*, *urticaria bullosa*." In urticaria, it is the deeper filaments of the cutaneous nerves which are affected, and that occasions, according to some dermatologists, spasm of the muscular tissue of the cuticle, whilst in erythema it is principally the papillary layer that is affected. In urticaria, the redness of the cuticle surrounding the wheals is due to hyperæmia, the elevation of the epidermis, which is called a wheal, to fluid; and this latter state was considered by the late Dr. Buchanan to arise from a circumscribed œdema of a cluster of capillary loops, springing from a common stem, and under the influence of a common nervous twig. From this cause the epidermis may be raised, either in the form of vesicles or bullæ, the former in connection with the distribution of particular nerves, being called herpes, and the latter, from its size, pemphigus. Mr. E. Wilson[4] has remarked that "pemphigus may be complicated with herpes; indeed the smaller bullæ of this disease bear a considerable resemblance to the vesicles of herpes phlyctenodes, and the likeness to herpes is still further increased by the occasional appearance of the small bullæ of pemphigus, in the form of rings;" and in the late epidemic in Dublin of cerebro-spinal meningitis, herpes and pemphigus were observed together, complicating the disease.[5] In consumption, the excessive sweating is evidently due to nerve-paresis, and I may mention that I have found no medicines more useful to check it than large doses of tannin, combined with quinine. The following remarks of Dr. Handfield Jones[1] are extremely interesting:—"The fact is of much significance, that in tolerably vigorous persons, the application of a linseed poultice produces only a macerated state of the epidermis, whilst in the weakly it gives rise to well-marked eczematoid eruption. The influence of the vaso-motor paresis in promoting perspiration is shown by many facts, as the occurrence of profuse sweating during sleep in phthisical, rachitic, and other persons. The same results from strong exercise, where the nerve-force is used up by the muscles, and to a much greater degree in those who are in training. By a statement made in a report from the Vienna Hospital, that when the sympathetic nerve is divided on one side of a horse's neck, that side of the face and head appear bathed in sweat. The occurrence of sweating and vesicular eruption as co-results of nerve-paresis is illustrated by a report given by Schrann respecting genuine intermittent fever, in the Upper Palatine, in 1856. The cold stage was short, while an abundant sweat came on early, attended with an eruption of herpes of varying intensity, which occupied the abdomen and forearm, and appeared to be rather *the cause* than the consequence of the sweat. In the above-mentioned instance, the vaso-motor nerves alone, or with the sensory, seem to have been directly affected; but the same phenomena, or very similar, may be produced by inhibitory (reflex) irritation."

A short time since, I admitted a boy, aged 12, at the dispensary for skin diseases, who first suffered from urticaria, which gradually disappeared. Labial herpes and pemphigus of the lower extremities then ensued; for, according to Dr. Burgess, the same exciting cause will produce different kinds of cutaneous diseases in different individuals. Thus, certain substances which suddenly derange the organs of digestion, sometimes produce urticaria, sometimes erythema or roseola. The form presented by an eruption is no criterion as to its cause. In many instances urticaria is nosologically identical with erythema, as is proved by their occasional occurrence in the same person, from the same cause. In other instances, urticaria is a reflex irritation proceeding from some important organ, usually the stomach or uterus, and under the control of a plexus of the sympathetic system. Dr. Russell[2] has published a case of a female, aged 23, affected with pemphigus. Every attack was preceded from a few minutes to an hour by itching, accompanied with pain; the part about to be affected appeared perfectly healthy until the eruption was becoming developed, when a raised red spot became visible, at the apex of which effusion quickly took place, a bulla forming, the pain then began to moderate. The exciting cause of herpes, or pemphigus, may be from exposure to cold and wet, pemphigus being often observed in barge and lightermen, who are, from their occupation, frequently wet for hours, especially their lower extremities. In these individuals the cutaneous eruption is often of a mixed character, if I may so express myself—viz., bullæ and vesicles, when the latter, a considerable area of the skin may be covered by the eruption. The origin of pemphigus in these men is considered to be due to cutaneous imbibition; but I think that exposure to cold and wet, which paralyses the nerves of the part, and the capillary vessels thus losing their tone, allow of the escape of the more fluid parts of the blood, is most probably the chief cause; in other words, a paresis of the vaso-motor nerves takes place, for, according to Dr. Brown-Séquard,[3] if the nervous supply of a part be injured, the blood-vessels become dilated, and the temperature of the affected part is increased. That herpes may arise from exposure to draughts of cold air, &c., is well-known, the eruption being preceded by neuralgia. In common catarrh, herpes of the lips is a common symptom, and this eruption has also been observed alternating with asthma; indeed Trousseau[4] states, on the authority of Dr. Duclos, that nearly all asthmatic subjects present a herpethic diathesis. Dr. Woakes, in a paper on the "Correlation of Cutaneous Exanthema with Neuralgia,"[1] records cases of herpes arising from the exposure to a cold wind. One case is especially interesting—a little girl, aged 3, took a long journey in a waggonet during the prevalence of a cold north-easterly wind. Though well covered in front, it escaped observation that the seat against which the child leaned was open at the back, and the short skirts of the child, resting on the seat allowed an almost uninterrupted admission of cold air to her waist. The following day, although previously in good health, a dense streak of herpes began to make its appearance round the left half of the body, about the line of junction of the child's skirts, and the more closely fitting portion of its attire.

Allusion has been made to the fact that herpes zoster is frequently preceded by neuralgic pain in the part about to become affected, and it is interesting to note that Heberden was aware of this, as in the following case—"In a woman, more than 50 years old, the herpes appeared upon the right clavicle, together with fever and pain throughout the whole right arm; the eruption and fever continued some weeks, but the skin remained scaly for several months, and the whole arm gradually became weaker, till it lost all power of motion, and in this state continued at least three years, and probably her whole life. The fingers were constantly in an involuntary tremor." Brodie and Watson have noticed more or less inflammation accompanying neuralgia; and, according to Dr. Handfield Jones,[2] Dr. Anstie has seen a well marked erysipelatoid condition developed under the same circumstances.

Vesicles are defined by Hebra[3] to be elevations of the horny layer of the epidermis by transparent or milky fluid. "An essential character of the vesicle is its size, for only those elevations of the epidermis, which are in size between a lentil or a millet seed, receive this appellation, all those larger are reckoned as bullæ." This latter elementary lesion is considered by the same author to have its seat in the epidermis between its mucous and horny layers, and are found "both at the aperture of hair sacs and in the inter-follicular spaces, bullæ, or blebs, are distinct from vesicles *simply by their magnitude*." In another part of his work the same author states that the first formed cluster of vesicles are always nearest the nervous centres, and that those which subsequently develop themselves lie more towards the peripheral distribution of the corresponding nerves.

The following are Dr. Handfield Jones'[4] views of the pathology of herpes zoster:—"Some morbid matter or influence strikes the cutaneous branch of an intercostal, or other nerve, and affects both the sensory and vasal nerves, paralysing them. The alteration produced in the former conditionates pain, which is a mode of sensory paralysis. The alteration of the vaso-motor nerves gives rise to hyperæmia and vesicular eruption. Nothing is of course more common than the neuralgic affection of the sensory nerves, the vaso-motor remaining exempt, yet we have not unfrequent examples of the latter becoming involved in the paresis of the former."

Herpes zoster resembles urticaria in its connection with the nervous system, being now understood from the observations of Dr. Von Bärensprung to be occasioned by irritation of the spinal ganglia, the posterior roots being implicated,[5] and, according to Trousseau, in neuralgia, a disease intimately connected with herpes, there is always tenderness on pressure over the spinous processes of the vertebræ accompanied by cutaneous hyperæsthesia at the point of exit of the nerve trunks.

[5] Herpes zoster has, according to Dr. Eulenburgh, always a peripheric origin, and consists of a characteristic change in the skin, with an accompanying affection of the vaso-motor system of nerves, and not as Von Bärensprung insists, in a primary affection of the spinal ganglia. In no case is it the rule that zoster follows the whole course of a certain spinal nerve, frequently only a single twig, and certain branches of the plexus are affected, which sometimes is observed in the neighbourhood of individual branches of a plexus (for instance, the brachial) with interruption of motor power in the corresponding nervous branches, complicated with paralysis of individual muscles. He records a case of a shoemaker, in which the symptoms were as follows:—Neuralgia, then

That the wheals in urticaria contain fluid has been proved by the simple experiment of G. Simon, who passed a needle into one, and subsequently observed fluid to ooze from the puncture, and the vesicles of herpes zoster are nothing more than small bullæ, the only difference between this disease, herpes, and urticaria is that in the former the œdema ends in serous exudation, which elevates the cuticle in the form of vesicles or small bullæ, whilst in the latter, the effused fluid is in less quantity, not so superficial, and gives rise to the appearance known as wheals.

M. Dumontpalier[1] has reported a case of intermittent urticaria, in which the attack appeared each night for six weeks; and it is interesting to note that different members of the same family had each some nervous affection—the parents were asthmatic, the grandfather rheumatic, the grandmother had angina pectoris, the brothers were rheumatic, and four children suffered from intermittent diarrhœa.

The observations of Trousseau[2] on the connection of asthma with cutaneous eruptions is of much interest—viz., that asthmatic subjects usually exhibit in their youth eruptions of an eczematous or herpetic character, "indeed, nothing is more common than to find herpetic, rheumatic, gouty, and hæmorrhoidal affections transform themselves into asthma. . . . Thus, eczematous eruptions, rheumatism, and gout are complaints which may be replaced by asthma, and may replace it in turn." Asthma, as is well known, is a neurosis.

Mr. E. Wilson[3] has recorded a case of traumatic eczema, which occurred in the person of a volunteer at a review from a "kick" of his rifle on the shoulder, and upon which he rubbed tincture of arnica. In the course of a few days the disease (eczema) appeared on his groin, as well as on his shoulder. The tincture of arnica, probably, acted as an irritant; and the irritation, Mr. Wilson states, excited in the injured part is propagated by the injured nerves to the cutaneous branches at a distance, the mechanism of nervous reflex function is set in motion, and papular and vesicular eruption with pruritus are developed on parts of the body at a considerable distance from the focus of irritation.

Mr. Hooker[4] has published a case of a neuralgic affection of the leg, complicated by superficial ulcers, and which was cured by division of the popliteal nerve, derangement of the digestive organs, suppressed menstruation, &c., have caused the appearance of herpes and pemphigus—in fact, the same set of causes as in urticaria, only that this latter disease is more intimately connected with the function of digestion and assimilation. Pemphigus usually occurs in debilitated subjects, frequently from intemperance, is secondary to some constitutional derangement, occasionally arises from local causes, and has been observed to co-exist with urticaria; indeed, Hebra[5] has described a case of urticaria, in which several of the wheals passed into bullæ.

From the preceding remarks, it will be evident that there exists an intimate connection between certain cutaneous diseases, especially as regards their origin. This group might be arranged, as follows :—

1. Erythema.	2. Herpes.
3. Pemphigus.	4. Urticaria.

For instance, we have in erythema, redness of the skin, and fluid effused into the subcutaneous tissue, especially in chronic cases; this effusion may elevate the cuticle in the form of wheals, and which, pressing on the cutaneous nerve filaments, gives rise to tingling; the disease may now be called urticaria. The effused fluid may increase in quantity and elevate the epidermis either in the form of vesicles (herpes) or bullæ (pemphigus). After the disappearance of these symptoms, the infiltration may still remain accompanied by itching, and leads to the establishment of an eczema; all these symptoms may be called the rebound of nature against irritation either internally or locally, which signifies in other words reaction, and which may become permanent, as in chronic urticaria, for all chronic diseases are liable to exacerbations.

Dr. Haughton[1] has well described this condition as a series of continuous vibrations against a cause which was formerly operative, but which has long ceased to have a real and tangible existence. A familiar example of the principle in question is the sensation as of sand in the eye, after the offending particle has been removed, as is also the common feeling as of pain in the foot, felt by men whose legs have been amputated.

And now, in concluding my rambling paper, I hope that the preceding remarks, in which the observations of others are freely made use of, may direct our attention to the morbid process going on in the lungs, and occasioning many cutaneous affections, and also furnish us with a hint to their successful treatment.

---

anæsthia and cramp in those parts to which the ulnar nerve is distributed, diminution of sensibility; and, lastly, herpes zoster, with distinct localization to the course and distribution of a cutaneous branch. Primarily, here we have the affection of the ulnar nerve, apparently rheumatic or perineuritic; from this arose diminution in the conducting power of the scissory and motor portions, and loss of function of the vaso-motor and sensory fibres which supply the skin, and hence the zoster.—*Edinburgh Medical Journal*, No. CLXI., June, 1868.

ON SOME POINTS CONNECTED WITH THE OPERATION FOR HARE-LIP AND EXCISION OF THE LIP FOR CANCER.

BY RD. J. KINKEAD, A.B., L.M.T.C.D., L.R.C.S.I., &c.

THE operation for excision of the lip for epithelioma (being almost identical with that for hare-lip, and treated of under the same head by most surgical writers) is, perhaps, one of the simplest and commonest in surgery; but it is also a most important one, for on its being skilfully performed, and the after-treatment carefully attended to, depends much of the future comfort and, I may say, happiness of the patient. Personal appearance being a subject so dear to mankind, that very few are philosophical enough to regard with unconcern the disfigurement of the natural beauty that each one of us believes that our own particular self is gifted with.

But its importance has, like most surgical operations, a two-fold bearing. The first, and most important, that relating to the patient, and just now treated of; the second, that relating to the surgeon. I know of no operation that will gain the surgeon, and the young surgeon especially, more credit if skilfully, or more discredit if unskilfully, performed than that for hare-lip or for cancer of the lip. The child is exhibited by its mother, the grown patient will point out his own lip: and each will tell how beautifully the operation was performed—how carefully the wound was dressed afterwards. No unevenness, no gap, in the free edge of the lip, little or no "mark" in the skin, no one, if not told, would have known that a piece of the lip had been taken away, or that there a hideous gap had before existed.

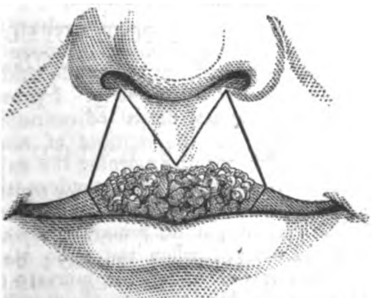
It is easy, on the other hand, to imagine how detrimental must be the censures passed where the edges of the wound are irregularly joined, where the lip is notched, and a broad cicatrix disfigures the patient for life.

Many deem that the most important part of the treatment consists in the revivifying of the edges of the fissure in hare-lip, or the excision of the diseased portion in epithelial cancer, and that the after-treatment of the case is trivial in comparison, but such is not the case. No doubt, the cutting part, the actual operation, is most important, but the after care of the case is no less so. The success of the most skilfully performed operation may be defeated by carelessness or ignorance with regard to the treatment of the wound after the operation.

The two following cases show this so fully, and besides contain many interesting points, such as the seat of disease in one case, the extent of lip removed, &c., that I need no apology in bringing them under the notice of the profession.

S. M'G., aged about 80, a farmer, called on me towards the end of August, 1867, to consult me about a sore lip. He gave me the following history :—About three years before a small sore came on his *upper lip,* he thought from sun-burn, but he did not mind it at first, thinking it would get well in winter, and in the first winter after its appearance it almost passed away, reappearing next summer, in a more aggravated form, again getting better in winter ; the next summer it was again worse, gradually extending from near the centre of the lip towards both angles of the mouth ; this winter it did not get better, but continued gradually to get worse till the date at which I saw it. For about six months the growth had been rapid, and the discharge annoyed him greatly.

The lip presented the following appearance :—Its free border was ulcerated for about three-fourths of its length, the commencement of the ulceration being about equidistant on both sides from the angles of the mouth. The surface of the ulcer had a warty appearance ; its edges were white and indurated. The induration and thickening of the lip spread for something more than one-fourth of an inch from the free edge of the lip towards the nose.



I operated on the 1st of September, 1867, in the following way :—

An assistant compressing the arteries at the angle of the mouth, I transfixed the lip from within outwards with a straight bistoury, at a point opposite the centre of the left nostril, about two or three lines below its orifice, and carried an incision in a right line (so as to include the cancer) towards the centre of the portion of healthy lip, between the angle of the mouth and the diseased part. When the knife had arrived within a line of the junction of the mucous membrane and skin, I here turned the blade inwards, and finished the incision as Druit recommends ; the raw surfaces of the cut forming at the termination an angle of about 100° with each other I made an exactly similar incision on the right side.

The diseased part of the lip was now supported by a portion equal in thickness to a half of each nostril and the columna nasi. Taking the diseased part in my left hand, I cut down on each side from the angles of the incisions at each nostril to the middle of the sustaining part, the cuts terminating at a point opposite the centre of columna nasi, and three lines from termination of the induration of the lip (about one-half inch from free edge). The disease had now been removed by what I may call a W-shaped incision. I brought the edges into exact apposition by means of three needles with sealing-wax heads, and a "twisted suture," laid a bit of wet lint over them, and as there was considerable strain on the suture, owing to the great loss of substance, I supported the parts by a long strap of adhesive plaster, extending from ear to ear. The third needle transfixed the V-shaped centre portion. Very little blood was lost.

On the 2nd, twenty-four hours after the operation, the wound seemed to have united throughout. No pain, no pus. He complained of nothing but that he said his mouth was too small, and asked me if I would not take out the needles and make it larger, as he feared the neighbours would laugh if his mouth was so small. The strain on the suture appeared to have disappeared.

On the 3rd, forty-eight hours after the operation, I withdrew two needles, but as the third was very firmly adherent I did not remove it till the next day.

On the 5th, I found the whole anterior portion of the lip in a sloughy condition. After being poulticed for a couple of days the slough separated, and showed that the mucous surface and about the posterior third of the lip were firmly united, and the anterior two-thirds, or that compressed between the ligature and needles, was that which sloughed; the V-shaped portion escaped.

The wound healed rapidly, contracting as it healed, and leaving very little more scar than would have been the case if it had united by the first intention.

The situation of the disease in this case was very rare, epithelioma as a rule attacking the lower lip.

Its situation, also, taken in connection with its size, made the operation more difficult than it would otherwise have been. If the same extent of the lower lip had been implicated I would have removed it by a semi-circular incision extending from one angle of the mouth to the other, tied the arteries, and brought the mucous membrane and skin into apposition by a few points of suture; but this method was inapplicable to the upper lip, as, owing to the immovability of the parts, a gap, the shape of the incision, would have left the teeth exposed and the patient unable to close his mouth (this would not be the case in the lower lip, the mobility of the skin over the chin being such that in twenty-four hours it would be hard for a casual observer to know, only for the suture, &c., that an operation had been performed). Under these circumstances I was compelled to leave as much as possible of the upper, or, if I may so call it, the nasal portion of the lip, as it was the most immovable, and hoping, also, that it would give support and take off some of the strain from the freed edge of the lip. This I was able to effect by leaving the V-shaped portion, and making the whole incision like an inverted W (*vide* woodcut). I finished the incision in the angular direction, in order that a prominence might be left opposite the line of union, to guard against a depression being left when the wound was healed, for the wound not only contracts from side to side in healing, but also in its length, so that if this precaution be not taken the line of the lip will not be perfect, and the patient will be more or less disfigured.

The next case is only interesting as exemplifying the lesson taught by the last, with regard to the length of time the pins should be left in.

M. O'S., aged 69, farmer. Had an epithelial ulcer, on lower lip, of moderate extent. On the 5th December, 1867, I removed the ulcer by the ordinary V incision, and brought the edges together by three needles similar to those used in last case.

On the 6th, exactly 23 hours after the operation, I withdrew the middle pin (which compressed the vessels) ; six hours after I removed the pin nearest the angle of the wound, and the following day the third pin, which was only used to bring the edges into exact union. The wound united throughout by the first intention, not a single drop of pus appearing. A small ulcer formed at the orifice nearest the point of the last pin withdrawn, a couple of days after its withdrawal.

In this case I withdrew the needles so soon, one in 23 *hours*, one in 30 hours, and the last in 48 hours, because I am convinced that the sloughing in the case of M'G. was occasioned by leaving the needles in too long, and that such was the case is shown by the posterior portion of the lip not exposed to the pressure between the needles, and the suture uniting at once, and not participating in the sloughing condition of the anterior parts between the two lower needles, and yet I left in the two lower needles only 48 hours, and the upper needle 72. Most surgical writers recommend the needles to be left in as long, if not longer, as, for instance, Liston says 48 hours, Erichsen 60 hours, S. Cooper 4 days, and Druit says that in 5 to 7 days is quite time enough to withdraw them.

In all cases where a large piece of the lip has to be removed, there must, of necessity, be a very considerable pressure of the lip between the hemp or silk of the suture and the needle, in order to get the edges to meet at all, and therefore there must be (and especially in old people) a great danger of killing the part, and losing, as in S. M'G.'s case, the whole portion by sloughing, or, as I once witnessed, the needles ulcerating out, and leaving not only the scar of the incision, but that, also, of each needle, which, to say the least of it, is not an improvement to the human face divine.

I would even recommend in many cases the needles to be removed in even a shorter period than 24 hours, as the hemp or silk of the suture is firmly cemented to the lip by the coagulated blood, &c., and will keep with the aid of a strip or two of adhesive plaster, the edges of the wound in firm apposition.

OVARIAN NEURALGIA TREATED BY HYDROCHLORATE OF AMMONIA AND TINCTURE OF ACONITE.

By J. WARING-CURRAN, L.K.Q.C.P.I., &c.

Whilst acute inflammation of the substance of the unimpregnated ovary is of rare occurrence, having never myself, in either hospital or private practice, met with what one would be led to believe a genuine or an established case, thus believing that the *ovarites* of writers on the subject is in character *chronic*, or perhaps in a few rare cases *sub-acute*, yet *neuralgia* of the *ovary* is far from uncommon. By neuralgia of this body, I mean that class of ovarian disturbance which Dr. Churchill has described under the nomenclature of "*ovarian irritation*," and to that which Dr. West applies the simpler designation of "*ovarian pain*," to me *ovarian neuralgia* appears a preferable and more correct term. Clinical observation has taught that the disease is independent of any local lesion, and more remediable by constitutional than any other method of treatment. My object here is not to enter into those cases of *ovarian neuralgia* dependent on defective moral training, and where a strictly moral treatment is to be enforced, and undue connubial excitement checked, but those cases where the patients' sufferings are constant and severe, when there is no hysterical temperament, and no obvious symptom of imprudence or immorality. My object, also, as briefly as possible, is to enter upon the treatment of such cases, and to illustrate, by the history of the six following, the great benefit to be derived from the muriate of ammonia and tincture of aconite in the treatment of this affection, when leeching, purgation, antispasmodics, vesicants, sedatives, internally administered and locally applied, had signally failed.

Case 1.—R. A., twenty-seven years of age, of sedentary habits and chlorotic appearance, unmarried, sought advice for a severe and constant pain suffered in the left iliac fossa; had been under another medical gentleman for ten days, from whose treatment she stated she had experienced no benefit. The pain was dull and aching in character, occasionally passing along the anterior surface and inner side of the thigh; has not slept for a week; the appetite is impaired, but the secretions are all healthy; the tongue has a characteristic nervous coating, and the pulse is quick; there is no hysteria. Upon examination, I find a fullness in the left iliac region, with tenderness. I ordered the application of liniment, belladonna, with chloroform, over the seat of pain; prescribed a saline aperient mixture, containing tincture of belladonna and a sedative draught at bedtime. For three days this treatment was persevered in, but there was no relief to the symptoms; the only ease experienced was when the patient lay flat on the face. I then applied a blister over the seat of mischief, gave opium, cannabis indicis, and camphor, in the form of pill, and tincture of conium in mixture. The following day there was an aggravation of the symptoms; the patient had spent a restless night, and the relatives became anxious. Upon this I prescribed an eight-ounce mixture, containing two drachms of the muriate of ammonia, with five-drop doses of tincture of aconite. The combination seemed to act magically; before the bottle was finished the pain was gone. Sulphate of iron and quinine was afterwards given, and four months have now elapsed without any return of the complaint.

Case 2.—A. L., aged 19 years, single, of a full habit, and hitherto healthy, became affected with a violent pain in the left groin, for which immediate advice was required, as the woman in attendance dreaded the existence of a hernia. On being visited I found the pulse high, and the usual symptoms of inflammatory fever. She had suffered severely four months previous to being visited, and had passed no water from the commencement of the attack; vomiting was a constant and distressing symptom. On examination I found slight swelling on the left side, with intense pain on manipulation; the tenderness extended below Poupart's ligament. Having satisfied myself that there was no rupture, I ordered turpentine stupes to be applied, and directed her to have a warm hip-bath, and a mercurial aperient. The following day, as there was no progress towards amendment, I applied six leeches over the site of pain. This gave temporary relief, but towards evening the pain became if anything more severe. I found her, on being visited, on her hands and feet out of bed, apparently suffering most acutely. I prescribed her a draught containing twenty drops of cannabis, and immediately placed her on the muriate of ammonia and aconite mixture. The ensuing morning she expressed herself considerably relieved, but the tenderness remained, and at times the pain recurred, producing vomiting when it did so. The patient got on remarkably well until the menstrual period arrived, when the same state of things occurred over again; but under the muriate of ammonia and aconite much was done to arrest the disease. She has had a menstrual period since without any recurrence of the pain.

Case 3.—A. R. F., aged 22 years, married for the last 14 months, has long suffered from chronic ovarian pain, increased during the menstrual period. Has taken, to use her own words, "no end of medicine," and has been under the treatment of various physicians, "who all told her the same thing." I prescribed at once the muriate of ammonia and aconite; two bottles in the course of six days entirely removed the pain. Six weeks have elapsed, a menstruation passed with little pain, and at the present time (July 14) I learn from the woman, who came with another patient, that she has entirely recovered, and has had no return of the pain since she finished the last mixture.

Case 4.—J. L., married, aged 40 years, has suffered from ovarian neuralgia for a number of years. At times the pain is unendurable; during its existence there is fulness and tenderness over its site. Having been under treatment for an hepatic lesion, and obtained the above information in the history of her case, I told her, when the ovarian neuralgia returned, to apply, and I should prescribe for its relief. She accordingly did so in the course of time, and from the muriate of ammonia and aconite she obtains almost immediate ease.

Case 5.—G., about 25 years of age, single, has suffered from the time of her first menstruation with ovarian pain, causing frequent and painful micturition, with vomiting. Gave her the muriate, and had the satisfaction of hearing her express that she obtained instantaneous relief after its administration. Has suffered from subsequent attacks, which invariably yield to the medicines advocated.

Case 6 is furnished to me by a professional relative. It is that of a woman, aged 30 years, who has borne three children, and has laboured under ovarian suffering for a term of years. She had been a constant patient of my informant. He had "exhausted the Pharmacopœia," as stated, but with no benefit. Upon the exhibition of the muriate and aconite, the symptoms directly yielded to treatment, and the woman was relieved much periodic suffering, and the physician re-established the confidence hitherto placed in him.

Although I am at a loss to account for the inexplicable property possessed by the muriate of ammonia in curing ovarian neuralgia, I can unquestionably vouch for its efficacy in the same way as the French and German authors first bore out its high character and undeniable specific action as a stimulant in mucous fevers, when the inflammatory symptoms have subsided.

P.S.—Since writing the foregoing, my attention has been directed by an eminent London physician, to whom I submitted the paper, to the exhaustive treatise of Dr. Prosser James, "On Sore Throat and the Laryngoscope," wherein I find that, in several recorded cases of tonsilitis complicated with ovarian neuralgia, aconite had been prescribed, and with success, by the distinguished author.

I had not the benefit of being previously acquainted with the book in question, and although I am ever ready to give honour where honour is due, I believe that this circumstance, together with the fact that the exact nature of the cases are materially different, does not deprive the above paper of its therapeutical importance, whilst an honest acknowledgment screens me from what the gifted candidate for the representation of Edinburgh and St. Andrews might feel inclined to look upon in the light of plagiarism, my motto not being "*Pereant qui ante nos nostra dixerunt.*"

◆

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

TWO CASES OF CHOREA TREATED BY THE ICE-BAG.

UNDER THE CARE OF DR. J. HAWTREY BENSON.

In the month of March last I brought under the notice of the Surgical Society of Ireland two cases treated successfully by means of the ice-bag, the report of which appeared afterwards in THE MEDICAL PRESS AND CIRCULAR for April 8th. One of these was the case of M. P., who had been suffering for about twelve months from incomplete hemiplegia of the left side, accompanied with choraic tremors. The disease had resisted all treatment both in the country, whence he came, and in the City of Dublin Hospital under my care, until its progress was arrested, and the disease greatly benefitted, by the application of Chapman's spine-bag. When admitted on that occasion into hospital, and for a month after while we used other remedies, the patient was quite unable to walk across the room without assistance, but after twenty-five days' treatment with the spine-bag, the use of the limbs was so much restored that he was enabled to walk up and down stairs, and the choraic tremors had so far subsided that he could raise a tumbler filled with water to his mouth, several times successively, without spilling the fluid—a feat which he could not have performed for more than a year previously. He left the house, however, before the treatment had been continued as long as I was desirous, and subsequently many of his former symptoms soon returned, but in a milder form than at first. In the following May, 1868, he returned to town, and I admitted him a second time into the City of Dublin Hospital.

I found on his re-admission that the paralysis had not altered much in its condition for the worse, since he left the house in July, 1867, but the choraic tremors had in great part returned, so that he was unable to undertake any employment necessitating the use of the left hand. These muscular movements were now almost confined to the neck, shoulder, and upper extremity of left side, and were most conspicuous in the extensors of the forearm. The fingers were jerked backwards continually, and with considerable force, either singly or in pairs, but rarely all together. The whole arm was occasionally drawn suddenly backwards or forwards, and sometimes the shoulder was involuntarily shrugged. He was enabled to flex the forearm at a right angle with the arm, but could scarcely separate the latter from the trunk. I immediately ordered the spine-bag to be applied for an hour and a-half twice daily, regulated the bowels, gave him cinnamon water as a *placebo* and put him upon full diet. This treatment was continued for about one month, during which he steadily improved, and by the end of that time the choraic tremors had almost completely vanished, and the use of the left arm was so far restored that he was enabled to raise his hand once more to his head.

Case 2.—E. M., a girl, æt. 13, was admitted into the City of Dublin Hospital on May 12th, 1868, suffering from chorea. She was well nourished, fat, and florid in complexion. Up to the commencement of her present illness, about three weeks previously, she had habitually enjoyed excellent health, with the exception of being subject to constipation. This, however, never produced any ill consequences, as far as she was aware. The origin of the chorea from which she was now suffering was referred, by her mother and herself, to her having used fatiguing physical exertion in lifting large buckets of water.

When admitted into hospital the muscles of the face, neck, extremities, and trunk were convulsed to a degree painful to witness. A female attendant was obliged to stay with her constantly to prevent her injuring herself against the bed-posts, or throwing herself out of bed. The tongue was furred; the pulse at the wrist could not be counted, owing to the subsultus of the neighbouring tendons; but, by placing the hand over the apex of the heart, the number of beats per minute were ascertained to be about 80. The action of the heart was very irregular, but no murmur was heard. The bowels had been confined for several days previously.

The ice-bag was applied, immediately after admission, along the whole length of the spine, and kept in its position by carefully-adjusted bandages. After one hour and a-half the bag was removed, as the application did not seem to be attended with the slightest benefit. She was then ordered a dose of jalap and calomel.

13th.—The purgative powder had acted well on the bowels during the night, but still the chorea, though somewhat moderated, was distressingly severe. The ice-bag was again applied, as at first, but before it was removed a most marked abatement of the choraic convulsions had taken place.

14th.—The muscular movements were about the same as at the time of the removal of the bag on the previous day. A dose of turpentine and castor oil was ordered.

15th.—The medicine had operated well, and brought away a large quantity of dark fœtid material from the bowels. The bag was again applied, and with a benefit almost equal to that experienced on the 13th. Menstruation coming on then interrupted the treatment, it being deemed not prudent to use the ice to the spine during the continuance of that function, lest it might be followed by some derangement, possibly by menorrhagia. Before the natural flow had subsided, however, the patient had so far convalesced that no further treatment was used beyond a few shower baths as a tonic.

She left the house in a week after perfectly recovered.

Observations.—The first case I have designated one of chorea, following the example of Trousseau. He did not confine that name to the disease called by Sydenham chorea sancti viti, but used it as a generic term to designate convulsive diseases, affecting any part or parts, no matter how local or how general, characterised by muscular agitation, or more or less strange movements and contortions, which were not distinctly admissible under any other head. Duchenne would, probably, have designated the affection of the forearm, where the mass of the disease seemed, at this his second admission, to be concentrated, as *functional spasm*, it being accompanied by paralysis, and being, probably, a consequence of the monotonous over-use of some of the muscles of the forearm in the practice of his trade as shoemaker.

Whatever its name be, the success of the treatment, in removing a second time the muscular agitations, and in affording a more free use of the limb, speaks highly in favour of the method employed, and, even if the benefit afterwards prove not permanent, it has, at least, done more than any other of the numerous treatments used with the patient.

Case 2 illustrates how the ice-bag may be useless as a sedative to the nervous centres so long as any eccentric cause of irritation exists, and how that sedative effect may be exerted when such cause is removed. In this case, doubtless, an accumulation in the bowels, or some irritating substance there, was the eccentric, reflex cause of the disease. But, even after the cause was removed, the disease continued till the sedative action of the ice rapidly restored equilibrium to the agitated muscular system, by operating on the disturbed nervous centres. No doubt the mere removal of the cause might have been followed by recovery, but the application of the ice, as we have every reason to believe, very materially hastened the event.

UNDER THE CARE OF MR. CROLY.

CASES OF BENT KNEE, IN WHICH DIVISION OF THE HAMSTRING TENDONS WAS PERFORMED—EXTENSION HAVING BEEN SUBSEQUENTLY EFFECTED: RECOVERY IN EACH CASE, WITH A USEFUL LIMB.

CASE 1.—J. F., a lad, aged 16 years, was admitted into the surgical wards, under Mr. Croly's care, suffering from contracted knee-joint.

History.—Five years previously, an abscess formed in the lower and outer third of the left thigh, and was opened by a surgeon. No cause could be assigned for the abscess, and the patient enjoyed good health up to that time; a year subsequently he fell upon his left knee, inflammation of the joint ensued, and the knee became gradually bent; he was obliged to use a crutch or stick in walking.

Condition of joint on patient's admission into the Hospital.—The internal condyle of the femur projects considerably inwards and forwards; the tibia is partially luxated backwards and outwards; the back of the condyles of the femur rest on the anterior edge of the head of the tibia; the patella is dislocated outwards; the hamstring tendons are tense; the muscles of the thigh and leg are wasted. The ends of the toes touch the ground; the heel is raised; the knee-joint can be flexed, but cannot be extended; the patient uses a stick, on which he leans when walking; his general health is good.

Treatment.—The limb was placed upon a well-padded McIntyre's splint, and fixed by a carefully applied roller. The screw of the splint (corresponding to the popliteal space) was turned gradually from day to day, so as to make further extension. This treatment was steadily persevered in for some days, and then Mr. Croly performed tenotomy in the following manner:—The splint having been removed, and the patient placed on his face, the tendon of the semi-tendinosus muscle, which was most prominent, was first divided, by passing the tenotome flatwise beneath the integument, and turning its edge against the tendon, which on division yielded with a crackling sound. The tendon of the semi-membranosus muscle then became prominent, and was also divided through the same wound; and lastly, the biceps tendon, on the outside, was cut in a similar manner, due care having been taken to avoid injuring the peroneal nerve; each puncture was covered with a small compress of lint, retained by adhesive plaster, and the splint was re-applied; no attempt at extension was made until the wounds had healed.

The patient suffered but little pain, and when all irritation had subsided, extension was made cautiously and gradually, by an occasional turn of the screw on the back of the splint, and in about twelve weeks the limb was almost as straight as the sound one. The McIntyre's splint was removed, and a starched bandage applied with pasteboard splint, to give additional support. The patient was supported by nutritious diet and a liberal allowance of porter, with cod-liver oil and syrup of iron. He was discharged from hospital, and is now able to walk without any artificial support. He works at a trade, and has almost as good use of the limb as of the sound one.

Case 2.—J. Q., a boy aged 16 years, was admitted into the hospital for contraction of the right knee, and inability to walk, except by the aid of a crutch.

History.—He fell when ten years old, and struck the patella. He suffered much pain from the injury. Inflammation and abscesses around the joint resulted. The knee became gradually bent, until at length he could barely touch the ground with the ends of his toes. He was received into an hospital in the city, but did not remain, in consequence, as he said, of amputation having been proposed to him.

State of joint and limb on admission of patient into the City of Dublin Hospital.—Right leg flexed, condyles of femur projecting forwards and inwards, the toes pointed and raised two inches from the ground, the heel six inches, the tibia thrown backwards into the popliteal space, the hamstring tendons prominent but not tense, the joint moveable. Flexion can be performed, but not extension. Two cicatrices are visible above the external condyle of the femur, the result of abscesses consequent on the injury. The boy is pale and delicate-looking.

Similar treatment as in case 1 was adopted—viz., McIntyre's splint, of suitable size, and well padded, and the same constitutional treatment, with subsequent division of the hamstring tendons, and cautious, gradual extension of the limb. In two months the knee became sufficiently straight, and the patient was discharged.

This young man is now engaged as a teacher in a school, and walks several miles daily, and uses neither crutch nor stick. The joint is *not* stiff. A cast and drawing of the limb were taken previously to commencement of treatment. The cast is preserved in the Museum of the Royal College of Surgeons, and the drawing is preserved in Mr. Croly's private collection. A photograph and cast were also lately taken, which show that the limb is almost as sightly as the unaffected one.

Case 3.—M. W., a girl, aged 5 years, came under Mr. Croly's observation as an extern patient, suffering from strumous abscesses around the left knee-joint.

History.—Her mother states that the child was in good health until about a month previously, when she complained of pain in the knee-joint. She limped, and kept her leg in the flexed position. The symptoms increased in severity, and she passed sleepless nights. Fomentations were applied without relief, and abscesses formed on inner side of the joint.

Appearance of child and condition of joint on admission into Hospital.—The patient presented the usual symptoms of hectic fever. The left knee-joint was enlarged, and the leg was flexed upon the thigh. The hamstring tendons were tense. The little sufferer screamed when any attempt was made to move the limb, for the purpose of examining the joint.

Treatment.—The child having been placed fully under the influence of chloroform, the limb was fixed upon a gutta-percha splint, which was moulded so as to support the joint. Liberal diet, with wine and quinine, were prescribed. The ulcers on the inner side of the joint were dressed with lint steeped in cod-liver oil. Under this general treatment the joint improved in condition, and all inflammatory action ceased. Mr. Croly then performed tenotomy, as in cases 1 and 2, and the limb was gradually extended.

The patient was discharged in one month, the joint being supported with a starched bandage and paste-board splint. The child is able to walk and place her foot flatly on the ground, and she has recovered her usual strength.

Remarks.—The foregoing cases are examples of false anchylosis of the knee-joint, resulting from injury, and subsequent inflammation, in strumous patients. In each case the tibia was drawn backwards by the action of the hamstring tendons, and the posterior part of the condyles of the femur rested upon the anterior surface of the head of the tibia. The patella was luxated outwards. The leg was flexed, and the foot everted. The limb in each case was not only deformed, but weak and useless to the patient. The cases prove the value of tenotomy and *cautious* extension of the limb (nearly to a straight line) *after all inflammatory action has been subdued.* The results were most satisfactory.

DR. STEEVENS' HOSPITAL.

CASES OCCURRING UNDER THE CARE OF MR. E. HAMILTON.

THE ANTISEPTIC TREATMENT.

IT is the manifest duty of every Hospital Surgeon to submit to the test of clinical practice, modes of treating disease which have been proposed in the advance of surgical science, in order to determine whether they are mere speculative innovations, or *bona fide* improvements.

There seems to be little doubt that the antiseptic treatment, as suggested and carried out by Professor Lister, will ultimately take its place under the latter head; but, as in the case of many similar discoveries, it will require time to sweep away old prejudices, and assert its true value, a few cases, selected at random from a great number which prove its utility, may not be uninteresting to those who still hesitate to adopt it.

A boy, aged 16, sustained a severe contusion in the left leg by the passage over of a car wheel. The skin was unbroken, and the bones escaped fracture, but there was extensive effusion of blood into the subcutaneous tissue. Attempts were made to promote its absorption by the continued application of cold lotions, and the use of saline purgatives. Inflammation set in, followed by suppuration, yielding a mixture of pus and blood most unfavourable for the ordinary treatment of abscess. The part was covered with lint, saturated with carbolic oil; beneath which it was opened, the water pressed out, and the aperture carefully closed with the carbolic acid putty and tinfoil, with the most satisfactory result.

A painter, aged 65, fell from a scaffold and sustained a compound fracture of the lower end of the humerus, extending into the joint. A portion of the inner condyle was detached, and removed through the wound. There was considerable oozing of blood, but no distinct vessel required hæmostatic treatment. The limb was placed in a bent position, the fragments adjusted, and the wound closed with the carbolic acid in linseed oil. As the parts lay well, and there was no pain or constitutional disturbance, the dressing was not removed for four days. At this time the wound had united without a trace of suppuration, and the progress of the case has been most confirmatory of the value of this treatment.

A female, aged 40, presented a tumour at the verge of the left breast, which had the character of schirrus in a marked degree. In consultation, its removal was decided on, but the presence of herpes zoster obliged us to defer it for a week. It was necessary to remove the skin over the tumour very freely, as it was discoloured. One or two small vessels were twisted. The wound was not washed with any antiseptic, but carefully sponged until all oozing of blood had ceased, and then accurately closed and covered with the carbolic acid putty. On the 4th day the dressings were carefully removed under cover of lint and carbolic oil—the sutures cut, and the putty re-applied. At the next dressing the cavity was filled, and the wound united without suppuration. In this case the temperature was accurately noted, and no elevation was observable at any time after the operation, nor was there any other indication of traumatic fever.

A man, aged 25, presented symptoms closely resembling those of acute rheumatism: severe pain in the larger joints, which ultimately became concentrated in the hip of the right side. The thigh was much enlarged, and the movements of the joint attended with severe pain. After some weeks, fluid was perceptible on the outside of the thigh: poultices were applied until the coverings became thin. It was then opened on the antiseptic plan; the fluid was greenish and unhealthy in character; the patient's system lowered by long confinement, yet no unpleasant results followed.

On the same day, in the same ward, for the purpose of clinical comparison, a large psoas abscess was treated with the drainage-tube, which was followed by very severe constitutional irritation. I candidly confess that the earlier trials which I made of the antiseptic plan, did not impress me favourably with it, but having had, through the kindness of Dr. Fleming, an opportunity of seeing Professor Lister himself demonstrate the *modus operandi*, and having since attended strictly to the minute details of it, and from what I have seen of the practice of others, I am satisfied that it will prove a valuable aid to the practice of surgeons; but to be successful, it must be applied and carried out with care and steady perseverance.

KING'S COLLEGE HOSPITAL.

CASES UNDER THE CARE OF DR. BEALE, F.R.S.

(From brief notes by Dr. TONGE.)

CARDIAC DISEASE.—M. F., æt. 21, nurse. Admitted September 17; discharged September 28. In hospital 11 days. *Unrelieved.* Cough, night sweats, dyspnœa, and slight hæmoptysis 1 month; increase of cough and dyspnœa one day. On third day after admission pulse 132, respiration 44, much dyspnœa and cough; slight gurgling at left apex; heart's action tumultuous; double bruit at base; two days later expectoration tinged with blood.

Quinine, dilute sulphuric acid, and liq. morphia; seidlitz powders.

CARDIAC DISEASE—TYPHUS.—Rebecca N., æt. 16, works sewing-machine. Admitted March 19; discharged May 6. In hospital 48 days. *Much relieved.* Three attacks of acute rheumatism, 6, 4, and 2 years ago; palpitation and dyspnœa on exertion 6 years; three attacks of angina, the last one month ago; lately cough, night sweats, emaciation, and œdema of legs. On admission very pallid, pain over heart and in left side; cough, palpitation, and dyspnœa; pleuritic rub at lower part of left side; loud systolic blowing at heart's apex, and loud diastolic bruit at base; urine one-third albumen. On third and fifth days after admission had severe angina—almost moribund in second attack; also much diarrhœa and vomiting (three days); frequent attacks of cardiac pain afterwards. On ninth day after admission, cough, expectoration, and sibilus over bases of lungs. Seven days later crepitation over both lungs, and some bronchial breathing and bronchophony over left side behind; pleuritic rub still audible.

Digitalis, carbonate of soda and bark; opium, sp. of ammon., aromatic and chloric ether; dilute muriatic acid and bark; iron and quinine.

Re-admitted August 11. *Died* September 9. In hospital 29 days. Has been at Walton since discharge; worse during last month; breath shorter; more pain and palpitation, and slight œdema of legs; heart's apex in sixth intercostal space half an inch to right of left nipple; pulse 126, full, slightly collapsing; loud blowing sound all over heart; trace of albumen in urine. Attacked with typhus about September 2. Much angina on 2nd, 3rd, and 4th. On September 5 pulse 136, respiration 44; intense headache, constant vomiting, marked rubeoloid and petechial rash on trunk. Death four days later.

Post-mortem.—Heart but little enlarged; mitral valve much thickened and very incompetent; many fibrinous deposits in spleen and kidneys.

Digitalis and bark; digitalis and iron; brandy; belladonna plaster over heart. On September 6, quinine, dilute muriatic acid and chloric ether; brandy to 12 oz.

Cardiac Disease.—Harriet C., æt. 42, married. Admitted May 24. *Died* June 7. In hospital 14 days. Acute rheumatism 28 years ago; occasional œdema of legs 19 years; cough and expectoration, and dropsy of legs 2 months; slight dulness and small crepitation at bases of lungs; faint systolic bruit at heart's apex; cardiac dulness increased; pulse 120, small; sleeps badly; orthopnœa; appetite bad. Four days after admission crepitation all over right lung, back and front, and dulness below scapula. Three days later much hæmoptysis; pulse 132, respiration 44; urine one-half albumen. Four days later patch of bronchial breathing below spine of right scapula; albumen two-thirds. Death next day.

Post-mortem.—Fluid in pleuræ; diffuse pulmonary apoplexy of lower lobe of right lung, and a circumscribed patch in left lower lobe; some emphysema; heart 13 oz.; right auricle greatly distended; mitral valve atheromatous; liver nutmeggy; cortex of kidneys wasted.

Chloric ether and aromatic spts. of ammonia; same, with juniper and henbane; conium and henbane; turpentine stupes.

Cardiac Disease—Bronchitis.—A. B., æt. 39, needlewoman. Admitted April 13; discharged April 30. In hospital 17 days. *Much relieved.* In King's College Hospital six months ago for bronchitis, under Dr. Beale. Acute rheumatism 19 years ago; slighter attacks since. Winter cough 6 years; palpitation 2 years; occasional œdema of feet; catamenia irregular; lately much præcordial pain extending down arms; occasional pain after food, and vomiting. On admission dyspnœa, cough and expectoration; rhonchus and sibilus at upper, and crepitation at lower, part of lungs; first sound of heart rough and prolonged; diastolic bruit at base; pulse 90, collapsing.

Carbonate of ammonia and senega (3 days); then sp. ammon. arom and mist. ammoniace; turpentine stupes.

Cardiac Dropsy.—J. H., æt. 64, laundress. Admitted November 15. *Died* November 19. In hospital 4 days. Never had rheumatism; subject to winter cough—this lately worse—and much dyspnœa; dropsy of legs 1 year; ascites 3 months. On admission face congested; legs erysipelatous; sloughing in places; great dyspnœa; heart very irregular; pulse 80, respiration 40; systolic bruit at heart's apex; dulness and fine crepitation at bases of lungs; urine albuminous, loaded with lithates; conjunctiva yellow.

Post-mortem.—Much fluid in peritoneum and left pleura, and a little in right pleura; pericardium adherent about apex of heart; heart 20 oz.; ventricles hypertrophied and dilated, especially left; mitral and aortic valves atheromatous; lungs gorged and emphysematous; liver and spleen large; left kidney fatty.

Squills, digitalis, and broom tops; gin 9 oz.

Cardiac Dropsy.—Emma P., æt. 29, married. Admitted September 27. *Died* November 11. In hospital 45 days. Scarlet fever 23 years ago; typhus 15 years ago; 5 years ago severe præcordial pain and palpitation, cough, and hæmoptysis (6 weeks). Now dyspnœa 9 weeks; dropsy 6 weeks; cough 1 month. On admission cheeks congested; considerable ascites; abdominal girth at umbilicus 36 inches; feet and ankles œdematous; præcordial dulness extending to third rib, and mid-sternum; heart feeble and intermittent; systolic bruit at apex; pulse 90, small; respiration 15; crepitation at posterior base of right lung. On October 26, abdomen 38 inches; urine scanty; respiration 40. The dyspnœa increased, and on Nov. 2, 200 oz. of fluid were drawn off from abdomen by tapping. Became delirious next day, and remained so till death on Nov. 11.

Post-mortem.—Much fluid in pericardium and peritoneum; lungs congested; heart 15 oz.; right auricle dilated; mitral valve very thick, and almost cartilaginous, and auriculo-ventricular orifice much narrowed; liver and kidneys congested.

Diuretics, stimulants, opiates, compound jalap powder.

Cardiac and Renal Dropsy.—C. R., æt. 45., married. Admitted April 20. *Died* on May 23. In hospital 33 days. Right hemiplegia in spring of 1863. Was in King's College Hospital 3 months under Dr. Johnson; regained some power over leg; memory worse since; swelling of legs 4 months; increase of dyspnœa and cough lately. On admission very corpulent, considerable anasarca; legs erysipelatous; mouth drawn to left side; tongue protruded to the right; complete loss of motion and partial anæsthesia of right half of face, and right arm and leg; orthopnœa; troublesome cough; pulse 112; respiration 32; rhonchus and sibilus, and coarse crepitation over lungs; systolic bruit at heart's apex; urine half albumen; the legs were punctured three times; albumen fell to one-third; gradually became exhausted, and died on May 23.

Post-mortem.—Left pleura full of fluid; lower lobe of lung carnefied; right lung gorged, and everywhere adherent; pericardium containing bloody serum, and covered with recent lymph; heart 18 oz.; left ventricle much hypertrophied; mitral orifice narrowed; one curtain of valve thickened; much fluid in peritoneum; kidneys greatly wasted; combined weight 5 oz.; granular on surface; urate of soda in tubes; old apoplectic cyst in left optic thalamus; inner and posterior part of thalamus softened; commencing atheroma of arteries at brain's base.

Liquor ammon. acetatis, chloric ether and sp. juniperi co.; dilute hydrocyanic acid and effervescing mixture; jalap and scammony powder; podophyllin; turpentine stupes.

Cardiac Dropsy.—George B., æt. 9. Admitted November 27; discharged February 11. In hospital 76 days. *Worse.* Never had rheumatism; pain about heart a year ago, after a fall down a well; dyspnœa and œdema of legs 7 weeks. On admission anasarca and considerable ascites; sloughing of prepuce; systolic bruit at heart's apex, double bruit at base; pulse 150, small, and collapsing; respiration 56; rhonchus and large crepitation all over lungs; dulness at bases; no albumen in urine; 12 days later bronchial breathing over right supra spinous fossa; 35 days later bronchial breathing at upper part of right lung, coarse crepitation over left lung; 19 days later right lung clear, coarse crepitation all over left lung. On 10th day after admission abdomen measured 32½ inches at umbilicus; 18 days later 25 inches; 3 days before discharge, 32 inches. Was removed by parents.

Aromatic spts. of ammonia; sp. junip. co., and decoction of broom tops; blue pill, squills, and digitalis. On January 2, liq. ammon. acetatis; chloric ether; sp. ammon. arom. and tincture of squills.

Ulceration of Larynx.—E. H., æt. 35, labourer. Admitted March 12. *Died* on March 12. No history. Almost moribund on admission; lips blue; face livid; extremities cold; breathing stridulous and difficult; pulse feeble, 120; operation refused by patient; death 3 hours after admission.

Post-mortem.—Bones and alæ of nose destroyed by syphilitic ulceration; slight adhesions of lungs, a few tubercles; bronchi clogged with creamy matter; upper half of epiglottis destroyed by ulceration; its upper margin level with arytenoids; its corners linked together by a fibrous cord containing cartilaginous nodules; false cords thickened; true cords gone; inner surface of arytenoids bare; trachea opposite first ring narrowed to the size of a goose quill, by a bridge of fibro-cartilaginous tissue on its anterior wall; tongue fissured and ulcerated.

Steam inhalation; brandy *ad. lib.*

Acute Bronchitis.—M. C., æt. 37, King's College Hospital nurse. Admitted March 3; discharged March 12. In hospital nine days. *Recovery.* Was admitted into King's College Hospital with cough six weeks ago, under Dr. Garrod. Discharged. *Much relieved* three weeks ago. Worse last two days; face flushed; cough, and scanty viscid expectoration; pulse 90, respiration 32; sibilus and a little rhonchus everywhere over chest; tongue furred; appetite bad.

Aromatic spts. of ammonia, chloric ether, and squills; turpentine stupes.

ACUTE BRONCHITIS—CHRONIC PNEUMONIA.—J. C., æt. 42. Admitted March 8. *Died* on March 8. Was in King's College Hospital for pneumonia, under Dr. Beale, last April. No history of present illness. Was admitted gasping for breath; extreme dyspnœa; profuse frothy purulent expectoration; coarse crepitation and sibilus over right lung, crepitation over left. Died 10½ hours after admission.

Post-mortem.—Firm, universal adhesion of left lung; pulmonary pleura very thick; substance of lung greyish and solid; sinking in water; right lung emphysematous, non-crepitant; bronchial mucous membrane very red; tubes choked with purulent matter; liver fatty, slightly cirrhosed; small stone in pelvis of left kidney.

Liq. ammon. acetatis, sp. ammon. arom., chloric ether and decoction of bark; mustard emetic; brandy *ad. lib.*; dry cupping to back of chest.

CHRONIC BRONCHITIS.—Louisa M'N., æt. 51, married. Admitted Jan. 15. Discharged March 2. In hospital 47 days. *Relieved.* Winter cough twelve years. Was in King's College Hospital last winter, under Dr. Beale. Previously ill seven weeks. Cough and expectoration; chest resonant; large crepitation at bases; *elsewhere sibilus*; pulse 102.

Carbonate of ammonia, squills, and senega; compound jalap powders; turpentine stupes; whiskey.

ACUTE BRONCHITIS.—Louisa M'N., æt. 51, married. Admitted May 13; discharged June 11. In hospital 29 days. *Very much relieved.* Since discharge on March 2 has been nearly free from cough and dyspnœa; previously ill 7 days; began with catarrh. On admission much dyspnœa; face dusky; pulse 96, respiration 36; physical signs of slight emphysema; dulness at right base; large crepitation all over both lungs; sputum viscid, moderately abundant.

Liq. ammon. acetatis, aromatic spts. ammonia, squills, and chloric ether.

ACUTE BRONCHITIS.—J. F., æt. 47, fur-skin dresser. Admitted September 30; discharged November 2. In hospital 33 days. *Recovery.* Had typhus many years ago; acute rheumatism 13 years ago; previously ill 12 days; rigors at commencement. On admission headache, soreness of limbs, slight cough, expectoration viscid and frothy; crepitation at posterior bases of lungs; pulse 88, respiration 28; tongue white, skin cool, appetite good, bowels confined.

Liq. ammon. acetatis and chloric ether; same, with carbonate of ammonia and senega; calomel and colocynth.

ACUTE BRONCHITIS—PHTHISIS.—Honora D., æt. 38, married. Admitted January 2; discharged January 23. In hospital 21 days. *Recovery.* Typhus 2 years ago; winter-cough 2 years; cough 3 months; loss of flesh 8 weeks. On admission, pulse 96, respiration 36. Rhonchus everywhere over chest; large crepitation over left side, in front; 9 days later, diminished expansion of upper part of right lung; dulness under clavicle and over supra spinous fossa, when gurgling crepitation, bronchophony, and harsh breathing are audible; elsewhere rhonchus and large crepitation.

Carbonate of ammonia, chloric ether, squills, and senega (11 days); then cod-liver oil, and syrup of iodide of iron. Brandy 4 oz.; turpentine stupes.

EMPHYSEMA — ACUTE BRONCHITIS. — O. E., æt. 13, newspaper-boy. Admitted January 22. *Died* on January 29. In hospital 7 days. Always short-winded. Was in King's College Hospital, under Dr. Budd, 9 months ago, for bronchitis. Previously ill 2 weeks, with increased dyspnœa and slight œdema of legs. On admission, face dusky; breathing hurried; much cough and puriform expectoration. Chest very resonant; no cardiac dulness; breathing harsh in front, with sibilus and crepitation at lower part; behind coarse crepitation. Heart's action rapid. Pulse 140; respiration 52. Five days later, dulness at left posterior base; sputa streaked with blood. Dyspnœa increased, and he died on 7th day after admission.

Post-mortem.—Lower lobe of right lung collapsed; upper lobe very emphysematous; patches of pulmonary apoplexy in left upper lobe; about o.i. fluid in pericardium. Auricular septum imperfect. Right cavities of heart somewhat dilated. Bronchial mucous membrane red. Stomach congested.

Aromatic spts. of ammonia, ether, and squills. Brandy 4 oz. Conium and henbane; pulv. scammon. co. Turpentine stupes and dry cupping to chest.

ACUTE BRONCHITIS.—J. D., æt. 27, porter. Admitted December 19; discharged January 27. In hospital 39 days. *Recovery.* Acute rheumatism 13 and 5 years ago; heart affected in second attack; short-winded; drinks 3 quarts of porter daily. Previously ill 10 days. Chest very resonant; rhonchus and sibilus over lungs; crepitation at posterior bases; diastolic bruit loudest at lower end of sternum. Pulse somewhat collapsing; 16 days later gout in left great toe and right ankle.

Carbonate of ammonia, chloric ether, and senega (19 days). Carbonate of ammonia, chloric ether, and liq. ammon. acetatis (5 days). Then carbonate of ammonia, sp. junip. co. and bark. Turpentine stupes.

REPORT ON WINE AND ITS ADULTERATION.

[SPECIALLY PREPARED FOR THE MEDICAL PRESS AND CIRCULAR.]

No. VIII.

IT is now time that we describe the process of testing wine to which we have so many times referred, and to which our last article was devoted. In doing so, we shall concisely state the steps as they are regularly taken at the Custom-houses, confining ourselves for the most part thus to the results of our experience on an immense scale, and which has been found thoroughly satisfactory.

The instruments figured and described in our last are of sufficiently moderate price to come within the reach of all of our readers who are inclined to experiment for themselves.

The first step in testing wine is to pour some of the sample to be tested into one of the receivers until the edge of the liquor is on a level with the upper division. This division is indicated by two short strokes, the lower for the actual surface of the liquor, the upper for the elevated ridge formed by the capillary attraction of the side of the vessel.

The measurement, *which should be very exact*, having been taken, pour the whole carefully and without loss into a still flask; then with a little clean water (it need not be distilled), rinse the receiver, and pour the rinsings also into the still flask, to insure having all the wine. The water thus added after measurement makes no alteration in the percentage result, and has the effect of protecting the flask from risk of breakage, as there is that extra bulk of liquor remaining after the spirit has passed over; while, should the flask be emptied by evaporation, it would be destroyed by the heat of the flame.

The flask is now to be screwed on to the neck of the condenser, and the lamp lighted and placed under. It should be observed that, in order to insure a steam-tight joint, a wash of vulcanised India-rubber is placed on the tube, and the pressure of the top of the flask against it when screwed into place, prevents any escape of vapour.

In this, as in all other experiments, scrupulous cleanliness is of great importance, and cannot be too strictly observed. With such care as we may anticipate our readers have learned during their chemical studies, there is little likelihood of breakage of the glass vessels employed, and altogether the process may be pronounced as simple as it is effectual.

The short time occupied by the method, its exactness, and the ease with which many experiments may be carried on simultaneously, commend it to the notice of all who desire to investigate the subject practically.

In a short time after the flame has begun to act on the wine, ebullition commences, and as soon as the first steam has heated the junction tube sufficiently to prevent condensation before reaching the descending portion, the distilled liquor flows from the delivery pipe into the receiver, which must be previously placed underneath with the spout well inserted to prevent loss. In some 8 or 9 minutes sufficient will have been distilled over to include the whole of the spirit; this, in light wines, under 26 degrees, is about one-half, and in stronger wines, two-thirds; but as a rule, the latter proportion is the safest to take for all kinds.

In boiling some wines, especially light French or Rhenish, of low quality, the bubbles of steam have great tenacity, and rise without breaking, so that, unless great care is taken in keeping the heat gentle, the wine itself will be carried over unchanged, and the operation nullified. In event of such a mishap occurring, the flask should be removed, and some plain water distilled through the condenser until the tube is cleansed of all trace of wine. This should also be done in any case if an operation has been stopped when the spirit was in transit, as another sample passed through immediately afterward would be rendered apparently stronger by carrying with it the spirit that would be clinging within the tube.

The distillate over, the next step is to dilute it to the bulk of the original wine. This is done with distilled water poured in carefully so as exactly to reach the upper mark. As any excess cannot be removed, it will be as well to pour in carefully from a bottle until it nearly reaches the point, and adjust the remainder with a pipette specially kept to this use.

The distillate is now poured into the trial glass, and the temperature and indication taken in the usual manner.

When Sykes's hydrometer is used, the strength per cent., as found in tables compiled for this purpose, and which is invariably under proof in the distillate, is then deducted from 100, and the remainder is the percentage of proof spirit in the wine under operation. Thus let the percentage strength found be 64·2 U.P., then 100—64·2=33·8 which is the amount per cent. of proof spirit in the wine, or, as called in the Act of Parliament, "Degrees of Proof Spirit."

In cases where the result is very close to the line dividing the classes, viz., 26, 42, or the degrees above this, especially if any doubt should exist, it will be necessary to take the wine and the distillate at the same temperature for the measurement. The most convenient temperature, in many respects, is 60°, but any other average point will do as well. If the temperature of the wine be much lower than that of the distillate, the result will be a greater proportionate strength: if higher, the contrary will be the case; for in the former instance, the wine, being condensed by the cold, will have more spirit bulk for bulk than at a higher temperature. If, then, the distillate be warmer, and consequently expanded in bulk, it will not require so much distilled water to dilute it to the bulk of the wine at starting, and the percentage amount of spirit will be proportionately greater. It requires, however, a large margin of difference of temperature to produce any important variation, generally speaking. In the custom's laboratories 60° F. is the temperature always used, and this is the degree to be recommended.

The true indication should be very carefully read, and if the stem of the instrument, on rising to its place after immersion, show the liquor standing in drops on it, as if from the repulsion of the surface, it should be gently wiped with a clean cambric or silk handkerchief, to remove any greasiness, or with the fingers moistened by the tongue, and in some instances a difference of two subdivisions deeper immersion will be afterwards observed; making an alteration of more than one per cent. A solution of carbonate of potass is a very excellent thing to cleanse the stem by gently rubbing it over with the finger and thumb, and then wiping with a soft rag.

To a careful operator the process is very simple and easy; care only and ordinary intelligence are needed to perform the whole correctly. Practice will give confidence and rapidity.

◆

CURRENT LITERATURE.

The second number of the *Practitioner* has appeared, and is fully equal to the first. It contains communications by Drs. Beale, Fraser, Hewitt, and Beigel, followed by several reviews, and the Clinic of the Month, with extracts from British and foreign journals.

Messrs. Longman have issued an entirely new edition of *Thomson's Conspectus*, adapted to the British Pharmacopœia. The mere announcement of this is sufficient to please all who have been accustomed to Thomson. The new edition is edited by Dr. Lloyd Birkett—an ample guarantee of its thorough revision, and is got up as a small 8vo., which can be carried conveniently in the pocket. The cloth cover is light and flexible, and the edges are cut and marbled. We hope other publishers will follow this example.

Messrs. Palmer and Howe, of Manchester, sends us a book on *Odontalgia*, by Mr. S. P. Shaw, which they have lately published.

We have also received the *fifth* edition of a pamphlet on *Water: its Impurities and Purification*, published by the London and General Water Purifying Company (157, Strand). Of course, it contains a full account of the Company's Cistern Filters, of which, after two years' use, we can report most favourably. At the same time there is plenty of other information in the pamphlet, and as it only costs 2d., it might be well for everyone to read it before purchasing a new filter. We suppose it is not necessary to say here that no one should drink unfiltered water.

Registered for Transmission Abroad.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 19, 1868.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

When the necessity for a change in certain particulars of College management forces itself on the minds of such men as Sir Thomas Watson and Dr. C. J. B. Williams, the Profession has a sufficient guarantee that such change is urgently required. They are men far above any suspicion of courting professional popularity, for they have long enjoyed all the advantages that great and honestly-earned reputation could bestow. Such men are too philosophically trained to allow an impulse to sway their judgment, and too experienced in knowledge of the world, not to foresee that without some change a coming *crisis* is inevitable. All are interested (and deeply so) in the coming event—the Fellows in upholding their scientific *status*, and the reputation for fair play, accredited to the large majority, and the members, in knowing that, in the future, neither favouritism nor prejudice will interfere with a proper recognition of their standing and their claims.

Most of our readers will, we think, agree with us that the time has gone by when the irresponsible Council of any College ought to be permitted to hold secret meetings for the nomination of Fellows. A Council ought to be placed beyond even the possibility of dealing unfairly with the College members. That some members of Council have heretofore dealt out their honours (?) "*without fear*," we can well believe, and would we could add, "*without reproach*."

The College of Physicians has tried, of late, to render itself a public professional institution; the Profession has, consequently, the right to demand an account of its stewardship, and an assurance that the College gates have not been so suddenly and widely opened either from selfish or other interested motives.

The large number of gentlemen admitted as "Licentiates" *ought* to regard their College as one in which, with the highest order, the highest honour should combine; but they may justly claim excuse for any laxity of discipline when they find that the good faith of some of their elder brethren assumes at times so questionable a shape.

In our opinion, the *real* reform needed is an entire change in the mode of election of the Council. Its members should be chosen by the general voice of the Fellows. So long as the system of self-election is in force, so long *may* abuses continue, and that abuses have been rife, is the almost unanimous verdict of the Profession.

THE MEDICAL COUNCIL—PARLIAMENT OR CONVOCATION.

The proposals for reforming the Medical Council grow more and more definite. It may therefore be well to keep an eye constantly on its constitution and its action. What has it done? what is it like? One reformer speaks of it as "our Medical Parliament." But does that phrase describe it?

Three bodies have lately concluded their sittings—Parliament, Convocation, and the Medical Council. Now, Parliament possesses great legislative power. Convocation little or none. Parliament has been called "a talking machine," but in this capacity is perhaps outdone by Convocation, as well as by the Council. Parliament professes to be the representative of the people, and in order to make it so has passed its reform bills. Convocation professes to represent the Church but is composed only of a small number of ecclesiastics. That is one reason why the nation will never give it any power. Now look at the Medical Council. It professes to represent the Profession, but really consists only of delegates from the corporations. Unlike Parliament it has refused to reform itself. It possesses considerable power in relation to the Profession, and so far may claim to be a Medical Parliament. It ignores a large part of the Profession, and spends most of its time in vain talk, and in these respects resembles Convocation. The Profession is much agitated at its shortcomings, and will infallibly insist on reform. Sick of talk and impotent resolutions, the practitioners of the country have come to the conclusion that they are not represented in the body they pay to support, and they demand their rights. We second their just and natural cry of indignation at the results of the last ten years, with their enormous cost, and ask whether they desire a Parliament or a Convocation? We know well enough the answer that will come from an immense majority, and we call on those who have determined to support no longer the present state of things to take sides in the controversy.

Is the representation demanded to be direct or indirect? That is a question several times propounded, but of less importance than some think. If the indirect method should be adopted, no one doubts that the Council would be more efficient, while every Corporation would also receive new life. We need corporate reform almost as the element of every reform. This point constitutes the beauty of the scheme put forth by Dr. Prosser James.

Its chance of success lies in the fact that it can be carried out without expense, and without legislation.

But there is something still more important than this, and which should unite all in its favour—viz., that it is not in itself necessarily antagonistic to the other plan. It would, in fact, be a stepping-stone to the other. We have never heard it alleged that indirect need supersede direct representation, nor are we aware that Dr. Prosser James has ever expressed himself as hostile to the plan of direct representation proposed by Dr. Andrew Wood.

This much is certain: the present Council is satisfied, with itself, though the Profession is dissatisfied with it. Let the Corporations imitate the University of Cambridge. so that the indirect plan may have a fair trial.

A Council elected in that manner would not only be more likely to give satisfaction, but would almost of a certainty reflect professional opinion, and that even on such a question as its own reform. It would also be more like a Parliament than a Convocation.

THE REPORTS OF THE MEDICAL OFFICER OF THE PRIVY COUNCIL.

Mr. Simon never fails to excite considerable interest by his annual reports, and the tenth of these important blue books, now before us, will be no exception to the rule.

This being the case, we beg to draw his attention to a fact respecting the series which is not very creditable to those who manage that department. We allude to the difficulty often experienced in obtaining copies, and their very unequal distribution. So much is this felt that we happen to be aware that a person is engaged in collecting copies under the idea that a complete set will soon be a curiosity. We have it, too, on the most reliable authority, that of one report only 150 copies were printed. Now, a work of this kind is national property. The expense of producing it is by no means slight, and, when once produced, surely the price of a little extra paper ought to be allowed in order to produce an adequate issue.

Again, some journals are provided with early proof-sheets of these reports, while others cannot have a copy before the public—then only by purchase; and sometimes there has been found a difficulty in getting them even by purchase. The writer of this speaks from experience, having found this unfair and unusual practice on the various journals which have done him the honour to request his opinion anent the blue books in question.

Of course we do not mean to say that it is the duty of the Medical Officer of the Privy Council to personally superintend the distribution of his reports, but we do feel that he is interested in having them widely distributed and fairly criticised in all quarters; and, for this reason, we ask his attention to the anomalies we have complained of. We are sure he will agree with us that all journals likely to comment upon the reports ought to be supplied with them as soon as they appear, just as publishers send their books for review.

He will admit too that press copies ought all to be distributed the same day, and that his subordinates who furnish in advance proofs of their communications or abstracts of them to favoured periodicals, are guilty of a breach of etiquette which would not be tolerated in other quarters. Such tricks tend to sap the foundations of all true criticism, and go far to make the reports less useful than they otherwise would be. Frequently, in this way, opinions obtain a certain illegitimate support, while those who differ, and *may possibly* be correct in differing, will not take the trouble to criticise what has obtained a one-sided endorsement in other quarters.

What we desire is, that the reports of Mr. Simon to the Privy Council should be as widely distributed as possible. We should like every Medical Officer of Health to be supplied with a free copy, as well as every journal likely to distribute a knowledge of them. We would gladly see these reports made the texts of able and conscientious essays by experienced writers, their value thoroughly sifted, and their facts made known to the whole thinking community. Let Mr. Simon say the word, and we feel sure it will be done. A few reams of paper, to utilise a large outlay, could not be grudged by the most thorough-going economist.

Again, some care might be taken about distribution. One medical friend of ours received gratis three copies of the most scarce report (of which only 150 were printed). But for his presenting us with one we should never have been able to get one at all. This speaks much for the necessity of a change. Perhaps some plan may be devised of ensuring that all who legitimately would use it should find no difficulty in having a copy at the public expense. That is the only way in which Mr. Simon can have justice done to his labours.

THE ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

Some of our readers may not be aware that a society under the above title has for some months past been in active operation. Its meetings are held monthly; papers are read on subjects bearing upon military medicine, surgery, and hygiene; officers in the army and navy, and medical men in civil practice in and around Portsmouth, are frequent visitors on those occasions, and altogether, while the society is calculated to bring the medical men of the army serving in that garrison into contact with the military officers in reference to questions which, as bearing upon the efficiency of soldiers, have a mutual interest to both, it is no less so to preserve that connection which should ever exist between the members of our own profession, whether in civil life or in the public service.

We are glad, therefore, to learn that the society in question gains in interest, and that its meetings are on each succeeding occasion becoming larger and longer. On the 5th of the present month, the most numerously attended one that has hitherto been held, took place at the Garrison Hospital, intimation having been previously circulated, that among other papers to be read on that occasion was one on "The Medical Transactions in the 33rd Foot during the late Expedition to Abyssinia," by Assistant-Surgeon Ball, of that regiment. The paper was an extremely interesting one. It detailed the nature of the medical arrangements made at Bombay, but which, as is usual, could not be carried out when actual service began; the nature of the country through which the force advanced from Zuolla to Magdala; the plants and animals that were observed; and gave many interesting particulars in regard to the various races of people met with. But what was of the greatest consequence in a professional point of view were the details which Dr. Ball gave in regard to the orders issued in Abyssinia itself, and other means to protect the health of the soldiers, and to provide for the requirements of such as fell sick or were wounded. It is, in reality, to the success of those measures that England is now indebted for the glorious and successful termination of the expedition. As well remarked by a contemporary: "had it not been for the exertions of the medical department on that occasion there would have been no army left to capture Magdala; no officers or soldiers to receive their well-merited honours and rewards." We wish that the army medical officers at our other large military stations would imitate the example set by their brethren at Portsmouth; and we venture to remark that by means of such societies they would do far more to elevate the departments of which they are members than by discussing in the public papers, as is too often the case, so-called "grievances," many of which seem only to exist because individuals condescend to notice, if not to seek for them.

If any encouragement were needed to induce Army Medical Officers to imitate the example upon which we are commenting, it would be found in the roll of army medical worthies from the time of the siege of Troy to our own day; and this kind of encouragement formed the introductory address with which the Portsmouth Society was opened by the principal Medical Officer of the station, Dr. Gordon, C.B., and which the society has printed and circulated. This address is before us, and, inasmuch as it epitomizes much, we would fain say to our army brethren, we hope it may be the subject of conversation at all the stations. It counts the bead-roll of fame of military surgeons, and enumerates the merits of some, that their civil brethren may, amidst the cares of practice, be apt to forget. Paré, Lowe, Woodall, Wiseman, Cleghorn, all these were army surgeons, as also, though it is seldom remembered, JOHN HUNTER. When we get another Guthrie in the Council of the College of Surgeons it is to be hoped he will be made Hunterian orator, and will take for his subject matters relating to military surgery, as elucidated by the labours of the great anatomist, physiologist, and surgeon.

If we continue our enumeration we cannot do it better than in the words of Dr. Gordon :—

"Donald Munro, an army surgeon, and cotemporary of Hunter, may be said to have placed the study of anatomy in the University of Edinburgh upon a scientific *basis*; and it may be mentioned here that he was the *first of four* generations of his name who in succession filled the chair which he in effect established.

"Then comes the name of Brocklesby, of whom we learn that he set to work to improve the wretched barracks and still more wretched hospitals, into which in his days the troops were crowded. He drew up a code of instructions for the preservation of health, and especially enforced the observance of cleanliness and good ventilation. To him the profession is indebted for the plan of treating cases of fever by means of liberal quantities of wine, in supercession of the bleedings and depletions that up to his time had been in use.

"I would remind yon that not until 1739 were barracks erected in this country for the accommodation of soldiers. Prior to that date the men lived in billets—chiefly in beer-houses and livery-stables; being there lodged in 'garrets, lumber-rooms, or back sheds fit for no other purpose;' absolutely without means of preserving personal cleanliness, and destitute of those conveniencies which are no less essential to bodily health than they are to morality.

"Such being the conditions, it will hardly seem credible to us of the present day that when in 1720 the first proposal to establish barracks for the troops was made, it was violently opposed; the people of London declaring that they wanted 'no red-coated nurses.' Perhaps, therefore, it is not to be wondered at that the buildings erected, after nineteen years of discussion, and, as we are informed, 'angry suspicion in the public mind,' were, as described by Dr. Brocklesby, 'low and ill-ventilated—calculated rather to generate than cure disease; and sweeping off the men like a perpetual pestilence.' To him, in conjunction with Munro, Pringle, and Hume, is due the credit of instituting post-mortem examinations, at a time prior to that when this method of investigating the action of disease was sytematically adopted in civil hospitals.

"Then came Dr. Girdlestone, who was the first to publish a work on *li*ver disease and cholera, as these affect British soldiers in India.

"Dr. Hamilton, also an army surgeon, who was the first to advocate the abolition of corporal punishment, saying regarding it, 'I wish it with all my heart abolished; it is an inhuman thing, more fitting the nature of savages than civilised and polished nations.' Such were the sentiments expressed by him in 1787.

"In 1791, John Bell, of the 26th Regiment, introduced into Military Hospitals a scale of diets, suited to the requirements of sick men, instead of the salt pork and beef which prior to that time had been the food allowed to the soldier, whether at his ordinary duties or prostrated with dysentery. He published a work on the causes which produce, and means of preventing disease in the West Indies—the title indicating the importance which he attached to hygiene; and to him, in a letter addressed to Earl Spencer in 1798, is due the first advocacy of one great school for military surgery. In that communication he entered into various details in regard to the subjects which, according to his views should be taught in such a school. These were anatomy, military surgery, military medicine, medical geography, including climates, seasons, the coasts of various countries; the manner of conducting soldiers in foreign expeditions, the general care of their health. the choice of encampments, the forming of hospitals on shore, how to convert churches and public buildings to this purpose. how to attend an army in the field, how to lay wounded in besieged towns, and how to carry them off the field in a retreating army. He would, moreover, have taught what he called military economics—as diet, clothing, exercise, general medicine, and all methods of preventing disease. Surely, it must be admitted that this army medical officer justly appreciated the importance of preventive medicine, or hygiene, as this branch of science is now more generally termed."

Space forbids or we would gladly continue our extracts, and show in detail how Robert Jackson wrote works valuable alike to the military and medical officer, and devoted much attention to the "health of troops," arguing that "health officers" were needed by armies in the field; how he was followed by Dr. Reide, who introduced statistical returns; how Dr. Rollo pointed out the means of preserving health in the West Indies; how Somerville produced a work embracing the whole subject of army hygiene; and how Lemprière, Borland, Pringle, Blane, Wright, Guthrie, Hennen, Thompson, Bellingall, Marshall, Millingen, Burke, and others carried on the good work which, we believe, is being continued by many earnest officers at the present day, who cannot fail to be encouraged by such societies as that at Portsmouth. Such examples as these, so felicitously sketched by Dr. Gordon, and the hearty approval and sympathy of their brethren in civil practice, we hereby cordially tender them.

◆

Notes on Current Topics.

Representation of the Profession in the Council.

This subject continually grows more important. Mr. Gamgee, in a very able speech at the Oxford meeting, pointed out the fruitlessness of the efforts of the British Medical Association and its deputation. The profession is gradually becoming educated, but it is a very slow process, and as yet there is no facility for quickening. What is wanted is an association of three times the strength of all the others, that exist, and as this is never likely to be attained, nothing remains but for the professional press to redouble its energies. The various schemes proposed for placing the Council on a satisfactory bases have never yet been fairly discussed by our contemporaries, and it is a sad indication of the condition of medical journalism, that in some quarters an attempt has been made to smother the full expression of opinion that has already been evoked.

For the honour alike of the profession and of journalism, we rejoice to add, the bad example is producing its own well-merited punishment, while the life it attempted to strangle is more vigorous than ever.

Medical reformers must be up and doing, they must no longer wait for the sound of the trumpet to waken them as of old by its warning voice. *Tempora mutantur.* We have now fallen on evil days. New leaders must be chosen for the new campaign, or it well assuredly be lost.

Let all who see the signs of the times rally around the few who are prepared to lead the way.

The Fellowship of the Royal College of Physicians of London.

Our anticipations have been realized so far as the late election of Fellows is concerned, but happily a movement has been commenced that is not likely to be arrested.

It has been proposed by some of the most distinguished Fellows that the Council should not be all-powerful in promoting its friends. Those who are disposed for reform would effect it by giving the body of Fellows at large the opportunity of proposing names for promotion. Dr. Williams and Sir T. Watson both agree as to the necessity ofthis, and, the refore, some hope remains. An authority, upon whom we rely, writes to us as follows:—

"The long delayed election of members to the Fellowship passed off this time without blackballing; but we may fairly presume that no expression of opinion emanating from so experienced and dispassionate an authority as Sir Thomas Watson, as to the time having come for a change in the mode of selection, will be lightly regarded. The mode in which the Council has hitherto managed matters may well be styled undignified and degrading.

"Some light, at least, has *now* been thrown upon the character of these secret meetings, and ugly rumours are afloat as to the reasons for some of the nominations.

"Indeed, the entire matter requires serious and public consideration. Evidently it is not much longer that this College will be permitted to continue to defy professional opinion so loudly and generally expressed.

"One thing is certain, that since the ventilation of the proceedings of the Council, the Fellowship is rapidly becoming estimated at its proper value, and that not of the highest to some of its possessors."

The Chair of Botany in the University of Dublin.

The Professorship vacated by Dr. A. Dickson (lately appointed Professor of Botany in the University of Glasgow) has already three claimants, and further competition for its occupancy may be expected. The candidates, who have as yet avowed their intention of seeking it, are Dr. Edward Percival Wright, Professor of Zoology in the University; the Rev. Dr. Browne, of Aberdeen, formerly a missionary and a well-known lecturer in popular science, and Mr. M'Nab.

Death of Dr. Mackenzie, of Glasgow.

Our record of the loss to the ranks of the profession of Mackenzie, of Glasgow, and our eulogium on his worth must be something more than a mere complimentary repetition of the trite phraseolgy of obtuaries in general, for we feel that in his death the very small phalanx of real, straightforward, sterling eye surgeons is reduced. Dr. Mackenzie's posthumous merits do not lie in great honours or a gigantic fortune gained in practice, though his career even in these directions was no ignoble one. It is in his sterling worth as a surgeon, that his name ought to live in the memory of the profession; it is because he stood firm to the erudition and experience, which great practice and an intelligent judgment had taught him, and did not allow himself to be carried away by the overwhelming flood, of what we must take leave to call ophthalmological quackery, which has for many years almost swept practical eye surgery out of sight or recognition.

The surgeon and author, one of whose pages of clear, well-grounded information was worth volumes of the insubstantial Germanisms lately current, has lived to see the wane of the ophthalmologic craze—the infrequent *oases* of accurate theory and genuine practice left visible here and there in the watery waste of useless and mischievous guess-work. When half the ophthalmological disquisitions of the last ten years will have completed their mission in the chandler's and trunkmaker's, Mackenzie's work will occupy the choicest corner in the library of the oculist, and Mackenzie's name will be recollected as "a material guarantee" for what it contains.

The Medicine of the Future.

Sir James Y. Simpson, in his address to the new graduates, has drawn a picture of the medicine of the future which may at once inspire with hope and depress with doubt. He anticipates eradicating tumours without the knife, arresting hæmorrhage without ligatures, or even his own invention of accupressure, and hopes that other departments of human knowledge may make simultaneous and equal advances, so that, Governments interfering to protect their subjects from diseases that may be prevented, the generations shall succeed each other slowly—each attaining the full duration of existence. The learned Professor carried his audience with him by his eloquence, and it may be a good thing to enlist the enthusiasm of the young graduates, but the question returns whether we have sober reason for anticipating so much.

The Thames.

It would appear that Father Thames is not sure, even yet, to attain that degree of pellucid purity which has so often been promised. Recent analyses, by new methods, go far to show that the impurities of the river are much more serious than has been lately supposed, besides which, the grosser test of the ordinary passenger's nose has detected, during the late hot weather, a very disagreeable smell. Whence does this arise? is a question the chemists may be expected to reply to very shortly. The upholders of our sewage system assert that it must be from what is thrown into the Thames higher up, and not from any part of the sewage being washed back by the tide. Others are of opinion that both these sources contribute impurity. Whatever the cause, the fact having been made known, should lead to immediate action.

Yellow Fever.

Another mail-ship has come in with less than its compliment of persons who set out, in consequence of yellow fever having carried them off. The epidemic prevails at Islay to the extent of 23 cases per day.

Lima and Callao are reported to be in a more favourable condition. The late epidemic at these places destroyed 13,000 persons.

Real and Apparent Death.

The Marquis of Ourches, a French nobleman, with the view, we presume, of guarding against the possibility of the burial of living persons in a state of catalepsy or prolonged syncope, has presented £1000 to the Academy of Medicine of Paris, for a prize to the discoverer of an accurate means of distinguishing between real and apparent death. He presents this very liberal prize, on the condition that the means of diagnosis shall be open to non-medical persons, and that the sum be reduced to £200, if none but the profession can use it.

Vaccination.

The action of the Medical Council in respect to the introduction of vaccination into the medical educational curriculum, has had the effect of bringing that subject within the second examination for the Bachelor of Medicine Degree at the University of London. In future a certificate from one of the vaccinators authorized by the Privy Council will be required of candidates, and vaccination will form one of the subjects of examination.

The Onion as a Disinfectant.

A writer (Mr. Wolff) in a recent number of the "Scientific American" maintains that the volatile principle of the onion is capable of destroying miasmatic gases. He states that the juice of the plant will neutralise the poison of certain snakes, and declares that he has used the onion as a disinfectant in severe cholera epidemics on ship-board. Mr. Wolff says :—"Onions placed in the room where there is small-pox will blister and decompose with great rapidity; not only so, but will prevent the spread of the disease. I think, as a disinfectant, they have no equal when properly used ; but keep them out of the stomach."

Bathing.

In our remarks on this subject last week, the name of Dr. Christison was incorrectly stated instead of that of Dr. Christian as the author, with Dr. Sieveking, of the suggestions we published. We understand that the issue of these rules for bathers of the Royal Humane Society was effected at the request and cost of a benevolent lady well-known under the signature of M. A. B. as a contributor to our journal. We last year inserted suggestions from the pen of the authoress on the subject, which were very favourably received by the non-medical press.

Conveyance of Food.

The Society of Arts have, at the suggestion of their Food Committee, offered the following prizes:—

1. For an improved method of conveying meat by rail, the Society's *Silver Medal* and £10.

The object in view is to reduce to a minimum the deterioration which meat now suffers in its transit by rail. The principal evils to be avoided are—excessive changes of temperature, and injuries by pressure, by handling, exposure to dust, insects, &c. This prize may be awarded for an improved railway meat van or for a travelling meat larder suitable for railways.

2. For an improved method of conveying milk cans by rail, the Society's *Silver Medal* and £10.

The object in view is to reduce to a minimum the deterioration which milk now suffers in its transit by rail in the ordinary open trucks. The principal evils to be avoided are—the heating and shaking of the milk cans.

3. For an improved railway milk can, the Society's *Silver Medal* and £10.

The object in view is to reduce to a minimum the deterioration which milk now suffers in its transit by rail in the ordinary milk cans or "churns." The principal evils to be avoided are—the heating of the milk, and all motion within the can which may cause the buttery particles to separate.

Water Companies.

Mr. Simon, in his new report, makes a suggestion which, while it may enlist the sympathies of some, will not fail to astound, and even shock, others. He would make public companies pay heavy damages to any one they may have injured.

He sees, in fact, what all know as a familiar axiom on jurisprudence—that a wrong proved, a remedy lies; but he says "years may elapse before any aggrieved person, unless unusually rich and public-spirited, will be willing to incur considerable legal costs in testing his so doubtful claim to redress."

There is something more than this, however, to be considered. Most people are aware that Mr. Simon and his assistants have adopted as true, the hypothesis that the last epidemic of cholera in London was due to the contamination of one company's water. This, of course, would be a case for redress, and the Medical Officer of the Privy Council appears to think that the relatives of all who perished in that outbreak should be entitled to damages from that company.

So far, the logic is good enough, but the premises are in dispute.

Every one knows—at least every one whose reading has not been confined to journals that have so scandalously burked the truth—that there are plenty of authorities who regard the hypothesis in question as an unjustifiable assumption. Now, suppose for a moment Mr. Simon's views to be in full operation: the first point for a complainant to prove would be that the water in question was the sole cause of the case of cholera by which he suffered. We venture to say that no such proof satisfactory to a court of justice could be produced, and that in this case, therefore, Mr. Simon's remedy would not be practicable.

That companies guilty of *malfaisance* are responsible to law, railway companies have found to their cost; but then, the injury has been easily proved.

In the case of the water companies, everything rests on hypothesis, and men equal to, and even superior to, the advisers of the Privy Council have asserted that the hypothesis is inconsistent with the facts. They would be as ready to dissent from, as Mr. Simon is to subscribe to, the assumption. What, then, could a jury do? By all means let us keep a tight rein on companies, and for knowingly distributing poisonous water let us hold every director and every servant concerned responsible. But let us not leave facts, and try to legislate on hypotheses.

Sickness in Dublin.

The week ending the 8th instant has been an unhealthy one in Dublin, and as might have been anticipated, the great heat of the weather has produced its inevitable effect on the public health. The deaths numbered 144, or 25 more than the corresponding weeks of the last four years. The whole of this excessive mortality is chargeable to diarrhœa, which not only exceeded in frequency the preceding week as 32 to 18 cases, but that of the corresponding week of last year by 26. Two of the cases are registered as cholera, but we presume the real Asiatic type of the disease was wanting.

The Quarterly Examinations at the Royal College of Surgeons in Ireland commenced last week, and the first half or Anatomical Examination terminated on Saturday. Fifty-four candidates presented themselves, out of whom it was found necessary to reject ten. The quality of the answering was, however, on the whole, considerably better than was elicited at the last examinations. The second half or Surgical Examination has just commenced, and will probably last for the whole of the current week.

We have been requested to announce that Mr. Grimshaw, Fellow of the Royal College of Surgeons of Ireland, the eminent dental-surgeon, has retired from the active practice of his profession.

We have no doubt that this announcement will be received with regret by the members of our profession, whose working ranks Mr. Grimshaw has so long and so honourably adorned, and we believe all will honestly join in wishing Mr. Grimshaw a long enjoyment of his well-earned leisure.

What a delightfully refreshing phase in the great English social ceremonial of dining is the ice-pudding? How charmingly do its cooling qualities, and its luscious flavours replace the gusto of the "choleric meats" which precede it? How agreeable it is for the *gourmets* who revel in the luxuries of the *diner a la Russe* to learn that no ice-pudding can claim to have achieved the loftiest degree of gastronomic perfection, unless the fruit which flavours it is the habitation of a given proportion of maggots. A person named Welch, charged before the Birmingham magistrates for selling rotten pine-apples and maggotty melons, thus defends himself. He said that "specked" fruit was always used to make ice-cream and confectionary, and unless the fruit was rotten it would not make delicacies so well, as the juice could not be got from the fruit in sufficient quantities unless it was "very ripe." All fruit, pears, apples, and melons had more or less of maggots in them, and confectioners would not buy fruit unless it was rotten, as the officer had termed it, but which he (witness) only considered "fully ripe."

Between "Pure Leicestershire catsup," prepared from putrid livers; ice puddings from decomposed fruit; pastry from the scrapings of filthy butter firkins, and all the nameless horrors in which the dining public has been so kindly instructed by recent authors, the paradise of gluttons appears to be losing its attractions.

(*Qui fit mœcenas?*)—Who made Oscar Clayton, M.D., Surgeon-in-Ordinary to his Royal Highness the Duke of Edinburgh last week, and Extra Surgeon-in-Ordinary to his Royal Highness the Heir-apparent, before the second ringing of the Church bell? Who is the lucky rat that eats the malt that lies in the house that Jack built? Can their Royal Highnesses be supposed to be jointly moved by a sudden and irrepressible inspiration to place their lives and the succession to the throne of England in the hollow of Dr. Clayton's hand, or is our editorial vision so purblind, and our ear so deaf that we have all these years been insensible to the brilliant sunburst and the immortal fame of Dr. Clayton's genius? In abject and penitent submission we await the admission of the light, and in helpless obscurity we still puzzle over our enigma. Oscar Clayton, M.D., of a foreign university, Fellow (not by examination) of the Royal College of Surgeons of London, a worthy apothecary and general practitioner, does not seem to us the *only* eligible occupant of the pinnacle of court favour. Who is it that keeps the second latch-key of the back-stairs wicket of Marlborough House?

THE Registrar-General's returns are still unsatisfactory, although London exhibits a more favourable condition. Some towns show a largely increased mortality. Leeds gives the highest death-rate—41·2 per 1000. Bristol is at the top of the list. The 11 large towns rank as follows as to rates:—Bristol 24·0, London 25·8, Newcastle 26·2, Bradford 33·5, Liverpool 34·7, Sheffield 35·7, Birmingham 37·5, Hull 38·3, Salford 38·7, Manchester 40·3, Leeds 41·2.

It would thus appear that London is likely to soon again show the favourable return on which we have so often commented. A fortnight ago the deaths in the metropolis were 1885; the mortality then declined to 1665, and has now fallen to 1545. This is only 52 higher than the average for the last 10 years, corrected for the increase of population. Zymotic diseases were fatal in 593 cases, the average being 571. The deaths from diarrhœa were 294, against 384 the previous week; 270 out of the 294 were the cases of infants.

The highest day temperature at Greenwich was 90·5; lowest night temperature 52·8. Rain only fell once, and then only to the extent of 0·14 of an inch.

Army Medical Department.

EXAMINATION PAPERS.

ANATOMY AND PHYSIOLOGY.

Monday, August 10, 1868, 10 *a.m. to* 1 *p.m.*

MR. BUSK.

1. What spinal nerves enter into the formation of the cervical and sacral plexuses? Describe the general arrangement of the nerves in each plexus, and enumerate those proceeding from it.
2. Describe the urinary bladder, and its relations to the immediately surrounding parts; the differences of relation it presents in various degrees of fulness, and at different periods of life; the arrangement of its muscular fibres, and the character of the epithelium by which it is lined.
3. Describe the structure of the spinal chord (below the medulla oblongata); and state what has been determined experimentally with regard to the transmission of sensory and motor impressions through it.
4. Describe the prostate, its relations and structure.
5. Mention the varieties in the origin and course of the blood vessels, to be regarded in the operations of laryngotomy and tracheotomy.
6. State the peculiarities of the blood in the hepatic, renal, and pulmonary veins, respectively.

SURGERY.

Monday, August 10*th*, 1868, 2 *to* 5 *p.m.*

MR. POLLOCK.

1. What would be the immediate symptoms, physical and general, in a case, in which fracture of three or four ribs, with laceration of the lung, had occurred on the right side, and what would be the changes observed in the symptoms, under a favourable progress? Describe the treatment to be adopted throughout.
2. A man was wounded by a rifle bullet, which entered at the anterior margin of the deltoid muscle, and passed out behind the shoulder; in its course it comminuted the head, as well as an inch and a-half of the upper extremity of the humerus. State what treatment should be pursued in such a case, and what would be the probable result.
3. A boy, in attempting to walk on the top bar of a rail-fence, slipped, and fell across it, striking the perinæum: shortly after, much swelling and discolouration of the part was observed; nor could urine be passed when the desire to empty the bladder became urgent. State the nature of the injury; the treatment to be adopted; and what usually, is the ultimate result of such an accident.
4. Describe the symptoms, and course of a case of scrofulous disease of the upper cervical vertebræ (1st to 4th). At what period of life does it usually occur and what are the pathological changes observed after death?
5. Describe the symptoms of stone in the bladder. What are its pathological effects on the bladder and kidneys, if not removed? Under what conditions should the operation of lithotomy, or lithotrity, be preferred?
6. Describe the symptoms, and results of syphilitic iritis, if neglected. What treatment should be pursued to arrest its progress?

MEDICINE.

Tuesday, August 11*th*, 1868, 10 *a.m. to* 1 *p.m.*

DR. PARKES.

1. Give an account of the Malarious Fevers, including the presumed causes, the symptoms, and the treatment.
2. Give the stethoscopic signs of the following diseases: pneumonia; pleurisy, with effusion; hydro-thorax; pulmonary apoplexy; coincident constriction and patency of the cardiac mitral opening and similar conditions of the aortic orifice.
3. What do you mean by the terms anæmia, chlorosis, and leucocythæmia? Describe carefully the state of the blood; the condition of the various organs, and give the treatment in each case.
4. Mention the chief conditions of the urine whish are important for diagnosis, and describe a case of Acute Morbus Brightii in an adult man.
5. For what purposes are conium, belladonna, and henbane used in medicine? Mention the chief pharmacopœil preparations, and state what is known about the action of the active principles.
6. What are the chief diseases which may come on in the first week after confinement? Give the chief symptoms, and, briefly, the treatment.

NATURAL HISTORY AND PHYSICS.

Tuesday, August 11*th*, 1868, 2 *to* 5 *p.m.*

DR. THOMSON.

I. ZOOLOGY.

1. Enumerate the principal varieties of the human race, and state their distinctive characteristics and geographical distribution.
2. Describe the principal modifications in the form and arrangement of the placenta, and state how far its various forms are useful in classification.
3. Give the characters of the class cœlenterata; mention its primary divisions, and name a genus belonging to each.
4. What is meant by *spontaneous* generation? Give some account of the experiments which have been made to prove or disprove it, and of the arguments that have been used for and against it.
5. Give an account of the geographical distribution of some of the larger divisions of the *mammalia.*

II. BOTANY.

1. Give an account of the process of impregnation in phenogams.
2. Describe the structure and functions of *leaves.*
3. Contrast the reproductive process in *ferns* and *mosses.*
4. Give the natural characters of *grasses* and *cyperaceæ,* pointing out where they agree and differ.
5. What is the geographical distribution of the following families of plants?

Proteaceæ.
Melastomaceæ.
Magnoliaceæ.
Umbelliferæ.
Ranunculaceæ.

III. PHYSICS.

1. Describe the way to make a thermometer. How do Fahrenheit's, Reaumur's, and the centigrade thermometers differ, and how can observations made with any one of them be converted into the other scales? What precautions are necessary to get the true temperature of the air?

2. What are the different hygrometric conditions of the air? What is saturation and the dew point? Describe the kinds of hygrometer in common use.

3. Explain the cause of the trade winds, and of land and sea breezes.

4. Give an account of the arguments employed to show the convertibility of light into heat and *vice versâ*.

5. What is coal geologically and physically, and what are the principal products of its distillation?

6. Describe the process of brewing, and the theory of fermentation.

Correspondence.

REPRESENTATION IN THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Much confusion prevails about the Cambridge University. Dr. Ashe is not altogether right. He seems to regard the Senate and the large constituency as two distinct bodies. They are in reality one. The Senate is the elective body, and consists of all M.A.'s and all doctors who have kept their names on the books. The number exceeds 5400, as stated by our able representative in the Council, Dr. Paget. All these may vote at the election of Dr. Paget, and, therefore, our University is one of the most liberal bodies. If the other Corporations did as much the plan of indirect representation would be carried. The advocate of this plan would do well to revise his scheme so far as Cambridge is concerned.

The election by the Senate at Cambridge is really a fair illustration of the popular election for which Dr. Prosser James is contending in the Medical Corporations, and which exists in some degree in the College of Physicians. There is no intermediate smaller body to control the election at Cambridge, as Dr. Ashe supposes. The original constitution of the ancient Universities was very popular, and much of the popular spirit survives in the customs and regulations of Cambridge, and, I believe, of Oxford also. Almost nothing can be done without the consent of the whole body of the Senate.

These points are worthy the attention of Medical Reformers.—I am, &c.,

A MEMBER OF THE SENATE OF THE UNIVERSITY OF CAMBRIDGE.

"FISTULA IN ANO."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having lately seen several operations for fistula, and also having remarked the great difficulty the surgeon experiences in keeping the buttocks separate, the idea struck me that the operator might be greatly assisted by having a broad piece of adhesive plaster attached to each buttock as far up towards the anus as possible. When these are firmly attached, an assistant at each side of the patient making extension with ends of the plaster will, I think, effectually keep the buttocks separate, and thus facilitate the operation greatly. If some of the numerous readers of your valuable journal would make a trial of this suggestion, they would greatly oblige, yours obediently,

A MEDICAL STUDENT (Dublin).

LIST of Entries in the Register of the Branch Medical Council (Ireland), for the month of July, 1868:—

James Dunlop, Edenderry House, Lisburn, county Antrim, Lic. R. Coll. Phys. Edin., 1867, Lic. R. Coll. Surg. Edin., 1867, M.D. Qu. Univ. Irel., 1868; William Henry Goode, Finglas House, county Dublin, M.B., 1867, and Master-Surg., 1867, Univ. Dublin; James Chatterton, Ballynamote, Cork, M.D., 1868, and Master-Surg., 1868, Qu. Univ. Irel.; James Crawford, Templeton, Killashee, co. Longford, Lic., 1868, and Lic. Midwifery, 1868, K. Q. Coll. Phys. Irel., Lic R. Coll. Surg. Irel., 1868; Richard Dawson Bennett, Union Hall, Leep, county Cork, Lic. R. Coll. Surg. Irel., 1868, Lic. Apoth. Hall, Dublin, 1868; Patrick Thomas Lyster, King-street, Athlone, Lic., 1866, and Lic. Midwifery, 1866, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel., 1866; Frederick Fitzgibbon, Castle Selem, Rosscarberry, county Cork, Lic. R. Coll. Surg. Irel., 1867, Lic. 1867, and Lic. Midwifery, 1867, K. Q. Coll. Phys. Irel.; Patrick Murphy, Mitchelstown, county Cork, M.D., Qu. Univ. Irel., 1868; Charles Gore Purcell, Tramore, county Waterford, M.D., 1867, and Master-Surg., 1867, Qu. Univ. Irel.; William Henry Saunderson, Edenderry, King's county, M.D., 1868, and Master-Surg., 1868, Queen's Univ. Irel., Lic. Midwifery, K.Q.C.P.I.; John Joseph Crean, Glenview, Clonmel, county Tipperary, Lic. 1868, and Lic. Midwifery, 1868, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel., 1868; David John Forbes, 4, Grande Parade, Cork, M.D., Queen's Univ. Irel., 1867; Robert Henry Robinson, Parsonstown, King's county, Lic. 1867, and Lic. Midwifery, 1867, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel., 1867; James Maybury Beamish, Lahara House, Drimolegue, county Cork, M.D., 1868, and Master-Surg., 1868, Qu. Univ. Irel.; Edward Wolfenden Collins, 28, Harcourt-street, Dublin, M.B. Univ. Dublin, 1868, Lic. 1868, and Lic. Midwifery, 1868, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel., 1868; Henry Stannard, 18, Shelbourne-road, Beggar's Bush, county Dublin, Lic. R. Coll. Surg. Irel., 1867, Lic. 1868, and Lic. Midwifery, 1868, K. Q. Coll. Phys. Irel.; John William Moore, 40, Fitzwilliam-square, West, Dublin, M.B., 1868, and Master-Surg., 1868, Univ. Dublin; Francis Richard O'Grady, Churchfield, Ballyhannis, county Mayo, Lic. R. Coll. Surg. Irel., 1867, Lic. K. Q. Coll. Phys. Irel., 1868, Charles William Shaw, Castle Blayney, county Monaghan, Lic. R. Coll. Surg. Edin., 1868; Robert Little, jun., Combermere Lodge, Lifford, county Donegal, Lic. R. Coll. Surg. Irel., 1868; Patrick Lynch Walsh, Kilfinane, county Limerick, M.D., 1868, and Master-Surg., 1868, Qu. Univ. Irel., Lic. Midwifery, K. Q. Coll. Phys. Irel., 1868; William MacDonnell, Broadford, county Clare, Lic. R. Coll. Phys. Edin., 1868, Lic. R. Coll. Surg. Edin. 1868; James Francis Ryan, 9, Harrymount, Kingstown, county Dublin, M.B., 1868, and Master-Surg., 1868, Univ. Dublin.

THE Director-General presents his compliments to the Editor of THE MEDICAL PRESS AND CIRCULAR, and begs to enclose for insertion a list of candidates of her Majesty's British Medical Service who were successful at the competitive examination in February, 1868, and have passed through a course at the Army Medical School.—Army Medical Department, 11th August, 1868:—

Names.	Studied at	No. of Marks.
Lewis, T.	London and Aberdeen	5452
Dobson, G. E.	Dublin	4655
Fraser, J.	Belfast	4563
Williamson, N. A.	Edinburgh	4375

Eager, O. S.	Do.	2428
Parke, Duke	Do.	2379

MILITARY HOSPITAL ARRANGEMENTS IN PRUSSIA.—Professor Esmarch, of Kiel, has substituted the ordinary shirting triangle for the bandage which Prussians soldiers used to carry in their knapsacks. He has managed the triangle in such a way that the first dressing of wounds and fractures can, behind the firing line, be instantly applied, guns and bayonets being used as temporary splints. M. Wittmaack has sent to the exhibition of Kiel an oil painting representing an action, and the manner in which the triangle should be used. The picture has attracted much attention, and it has been ordered to be printed on each of the triangles given to the troops, so that they may, on the very linen used, see the manner of employing it.

EARLY PREGNANCY.—Dr. Horwitz was called to a pregnant girl who had scarcely reached her 12th year, and of whose age there could be no doubt. The menses first appeared during her 10th year and continued regularly. She went through her pregnancy very comfortably. The pelvis was well formed and capacious. The labour proceeded very favourably, and terminated in ten hours with the birth of a strong living male child. She went on very well, and had a plentiful secretion of milk. References are given to other remarkable cases of the kind on record.—*Petersburg Med. Zeitschrift*, 1867, No. 9.

How to Utilize Leeches.—The German doctors have lately been playing their leeches a droll trick—making one worm do the work of many. When the little blood-sucker has taken his fill and is about to release his bite, he is tapped; a small incision is made in his side, that serves as an outlet for the blood, and he goes on sucking, in happy ignorance of the cause of his abnormal appetite, as long as the doctor pleases. Bdellatomy is the name given to the practice, and it is urged that it is not cruel, but contrarywise, since it does the leech a good turn by enabling him to enjoy his rich feast indefinitely. He does not die under the operation, but with proper treatment is soon healed, and may be incised over and over again. There was once an alderman who wished he had been a camel, that he might have been blessed with the seven stomachs vouchsafed by nature to that animal. If such a gourmand still exists, let him seek surgical aid in some such treatment as that practised on the leeches, that he may eat and drink *ad libitum*, and feel no worse.—*Once a Week.*

Vital Statistics of the Navy.—The statistical report of the health of the Navy just issued gives a very favourable view of the sanitary condition of the force afloat in 1865. The total force was 51,210 men; the cases on the sick list numbered 69,315, which is in the proportion of 1368 per 1000 of mean force, being slightly below the ratio of the previous year. The total number invalided was 1687, or 32·9 per 1000, a reduction, as compared with the previous year, of 2·5 per 1000. Of those invalided 181 were for wounds and injuries. There were 580 deaths, 416 being the result of disease, and 164 of wounds, injuries, and drowning. The total death-rate was 11·3 per 1000 of mean force, which is a reduction, as compared with the preceding year of 2·7 per 1000. The mortality from disease alone was 8·1 per 1000. The lowest sick-rate was on the Mediterranean station, 33·4, and the highest on the China station, 80·4. On the west coast of Africa yellow fever was epidemic, and in China small-pox prevailed in the squadron at Japan. At the former station, fever increased the mortality to the extent of 28·4 per 1000. Cholera appeared in the Mediterranean, and occasioned great mortality among the civil and military population of Malta. The loss annually sustained by the navy from small-pox has caused Dr. Mackay to suggest the propriety of considering whether it may not be advisable to introduce a system of periodical re-vaccination into the service. The death-rate on the home station from disease was 5·8 per 1000, and from violence 1·3; on the Mediterranean station, from disease 6·2, from violence 2; North America and the West Indies, from disease 7·7, from violence 4·8; South-east cost of America, from disease 7·6, from violence 3·8; Pacific, from disease 3·8, from violence 3·4; West Coast of Africa, from disease 38·2, from violence 10; Cape of Good Hope and East Indies, from disease 9·4, from violence 5·5; China, from disease 17·7, from violence 5·5; Australia, from disease 4·4, from violence 6·2; and in the Irregular force, from disease 2·5, from violence 4·4.

Disease caused by Heat in America.—The number of persons reported as having been prostrated by the heat during the past 24 hours in this city, Brooklyn, and Jersey city exceeds 100. Over 50 per cent. of these have proved fatal. Dr. Harris, Registrar of Vital Statistics of the Board of Health, makes the startling announcement that 250 deaths are known to have resulted from the excessive heat of the past three days within the metropolitan district. The highest range of the thermometer in this city yesterday was 94. In Poughkeepsie it was 103, in Baltimore 102, in Montreal 105, and in Richmond, Virginia, 96. In a note addressed to the President of the Metropolitan Board of Health, on Wednesday afternoon, Dr. Harris, the Registrar and Corresponding Secretary of the Board, suggests the following brief precautions against sunstroke:—1. When exposed to excessive heat the natural perspiration or sweating must not be checked. Let the sweat flow, and do not throw off all the flannel garments. 2. Wash the head and neck frequently in cold water, and, if exposed in the sun, or in any very hot place, wear upon the top of the head, under a hat or otherwise, a light handkerchief or other thin folds of cloth wet with cold water. Remember that the head and neck must be kept cool, and also be free from the pressure of tight clothing. 3. If headache, dizziness, a feeling of tightness across the forehead, a failing of sight, or a feeling of weakness and prostration ('giving out') occurs, let the person immediately go to a cool place and lie down, with the back and the feet covered, and have a few quarts of cold water poured slowly upon the head and the sides of the neck. If the symptoms are not at once relieved send for the nearest good physician. 4. What to do until the physician comes.—If the patient is still sweating let him drink freely of cold black tea or coffee; tea is best. But if sweating has ceased there is very great danger. Then the head, face, neck, and entire chest should be rapidly sponged with ice-water, and a bag of powdered ice, well covered with a towel, should be kept under the head and the back of the neck; give a mixture of the carbonate of ammonia (hartshorn) and muriate of ammonia, eight or ten grains of each in water, every ten or fifteen minutes until the physician comes or until the patient rallies and sweats. Enfeebled, intemperate, poorly-fed, over-fed, and irritable persons, are most in danger of the fatal effect of heat. People who live and sleep in foul air and unventilated places, and who are overworked and underfed, and who use intoxicating drink, suffer greatly. Instead of intoxicating drink and the habit of morning and evening drams, let good black tea and coffee, and good, nourishing, and well-cooked food be regularly taken. Bathe the whole body early in the morning in order to have a clean skin and good natural sweating during the day. Labourers and others who have much to do should rise so early that they can have several rests and keep in the shade from eleven till four in these very hot days; and let this most important fact be remembered—namely, that by natural sweating (perspiration) the body is kept healthfully cool when exposed to these terrible heats, and that over-exertion, passion, and all kinds of intemperance must be avoided. In his note to the President of the Board of Health, Dr. Harris justly urges that the contractors, builders, and other great employers of labour should be urged to be considerate to their men, and give them the advice and the opportunity for rest which they now need. The fact that the first fifteen days of July have had an average or mean temperature ten degrees higher than has been experienced in more than 25 years shoul lead all our fellow-citizens to use every means possible to encourage or enforce sanitary cleansing and the observance of the rules of health. Especially should these suggestions concerning sunstroke be heeded."—*New York Herald.*

British Association at Norwich.—It has been for some time past generally known that an unusual influx of foreign *savants* is expected at Norwich this week. The following are some of the names most intimately connected with our own profession:—Dr. Carl Vogt and Dr. Appia, from Geneva; Professors Béhier and Broca, from Paris; Drs. Laage, Boorgaard, and Heinsius, of Leyden; Professor Favre, of Lyons; Professor Sartorius Walterhausen, of Halle; Professor Nilsson, of Sweden, etc., etc. Several of these distinguished professors have important communications to make, and will take an active part in the proceedings of this, the thirty-eighth annual meeting, which promises to be one of the most brilliant in the annals of the association. The first general meeting will be held on the 19th inst., at 8 P.M., when his Grace the Duke of Buccleuch will resign the chair, and Dr. Hooker, F.R.S., will assume the presidency and deliver an address. The International Prehistoric Society will also hold its meetings at Norwich during the week.

The amount of work which will here pass muster for a fair day's toil is far beyond what is expected of a man in Great Britain. This is no country for foreign idlers to come to. The Americans hate physical exertion themselves, and are willing to pay Englishmen, Irishmen, Germans, or anybody else to come here and do the hard work for them, but they will take great care to get as much out of the people they pay as can be either wheedled or forced from their bones. I have been very much struck here by the fact of the evident dislike of hard-work which animates the real American. If I have noticed a man in a workshop or in the open air driving at his work with a will and an apparent relish, as is so commonly seen in England, I have said to myself, that man's grandfather was not an American citizen; and upon inquiry I have seldom found that I was mistaken. The dry climate may have something to do with it, for I have observed elsewhere that dry climates do not seem conducive to an appetite for manual labour, but they seem to make people more nervously active than the denizens of a damper region.—*English Working-man's Letter in Daily News.*

The *Army and Navy Gazette* states that at the Curragh instructions have been received that, as a sanitary measure, patients in military hospitals are to be allotted 1200 cubic feet of space each, and arrangements are being made to give effect to these instructions as soon as possible.

Lecture.

IS THE ADMINISTRATION OF WINE IN ACUTE DISEASE A MERE FASHION?

By THOMAS WRIGLEY GRIMSHAW, M.D.Dub.,
LECTURER ON MATERIA MEDICA IN DR. STEEVENS' HOSPITAL,
AND ONE OF THE PHYSICIANS OF CORK-STREET FEVER HOSPITAL.

(Abstract of one of a Course of Lectures on Materia Medica and Therapeutics delivered in Dr. Steevens' Hospital during the Summer Session of 1868.)

Gentlemen—In yesterday's lecture I detailed the varieties of wine and fluids containing alcohol, classifying these fluids into weak wines and beers, strong wines, and ardent spirits. I pointed out to you that weak wines have peculiar tonic, and invigorating properties, independent of the slight stimulating powers which they possess, owing to their contained alcohol. I informed you that the stronger wines possess these properties, and that they also possess in a considerable degree the powerful stimulating and antiseptic properties of alcohol. I shall now proceed to direct your attention more particularly to the physiological and therapeutic effects of alcohol, or rather of fluids containing alcohol in sufficient quantity to give a special character to their action, and entitle them to the popular term of alcoholic fluids. The great characters of an alcoholic fluid are stimulant and antiseptic, and if given in excessive doses narcotic. The combination of stimulant and narcotic properties in the same agent is not new to you, as I have already in past lectures remarked on such a combination, especially in the case of opium. Alcoholic fluids, however, are seldom employed therapeutically as narcotics, but frequently as stimulants; whereas opium is nearly always employed as a narcotic, and seldom as a stimulant. You therefore in your classifications of remedies usually find opium in the list of narcotics, and alcoholic fluids in the list of stimulants. It is chiefly as a stimulant we have to deal with alcohol in these lectures, although I shall also have a few words of commendation to say of its antiseptic, and a few of caution to give, with regard to its narcotic properties. These considerations of the properties of alcoholic fluids, as well as when, where, and how they are to be made available in therapeutics, I shall leave for consideration in a future lecture, and I only ask you at present to take it for granted, that alcoholic fluids are stimulants (not of course denying that they are also narcotics). As alcoholic fluids are our main-stays as stimulants, and are in much more common therapeutic use at the present than at former times, I shall point out how it happens that they have come to occupy so important a place in our materia medica, as compared with that of our predecessors. The slight use made of alcoholic stimulants by the physicians of past ages must have depended upon, either the medical opinion of the day, or upon the kind of diseases then prevalent. If upon the latter, either diseases of former times differed from those we now meet with, or we are altogether wrong in our extensive use of stimulants; but we are not wrong (as, for the sake of argument, I shall now assume, leaving the proof to the next lecture), therefore diseases differ from those of former days, or medical opinions differ; and, assuming we are right in our opinions, the physicians of former days, from Hippocrates to Sydenham, and from Sydenham to our own times, must have been ignorant of the treatment of many of those diseases which they professed to know how best to cure; not only ignorant, but so grossly ignorant, that in many cases they pursued treatment which we know must have been absolutely injurious, and even dangerous. Can we possibly believe that such ignorance existed among those who have been first in the improvement of medical science; who, with small means at their disposal, were accurate observers of disease; and who, without chemical tests, stethoscopes, ophthalmoscopes, laryngoscopes, endoscopes, thermometers, or sphygmographs, clearly described symptoms and made accurate diagnoses—frequently as accurate as our own with all these aids of physical science? The answer is that these great men were not ignorant, and that they themselves have given proof of their knowledge in their works, which have come down to us. Not only have they proved their knowledge of, and ability to treat disease, but they have left sufficient evidence, that if they had had the same kind of disease to deal with in their day, as we have in ours, they would have followed pretty much the same principles as we do, and that in the administration of stimulants they did follow these principles. Although wine was not their commonest stimulant, yet they frequently used it, alone or in combination with other agents, or artificial cordials composed of many stimulants, sometimes including wine or spirits of wine.

The question of the use of stimulants by our predecessors is necessarily mixed up with the consideration of the use of agents of the contrary character, such as blood-letting, emetics, and other depressants.

Those who tell us that stimulants are useless or injurious accuse us of ignorance in their use, or of being the mere followers of fashion, and tell us it used to be the fashion to bleed, vomit, and purge patients in fevers, erysipelas, exanthemes, and inflammation of the lungs; now it is the fashion to give them wine, brandy, whiskey, and all sorts of stimulating agents, and that by this treatment we kill as many, if not more, than our predecessors, and that, on the whole, we are all equally bad (not equally good) with those who went before us. The answer is, that our predecessors were as good (considering the means at their disposal) as we are, and that we have not changed in fashion, but while following practice similar to that of our predecessors, disease has changed its nature (or fashion, if you like); that we deplete less, and stimulate more than they, because there are fewer to be depleted, and more to be stimulated than formerly; and, lastly, that it is not true that they gave no stimulants in cases similar to ours, but that they usually did give stimulants in such cases; and this I proceed to prove by reference to authors of past ages, remembering that the question of the use of stimulants and depressants are inseparably connected when we discuss their use in those diseases, which sometimes assume the sthenic, sometimes the asthenic (known by the various terms putrid, putrescent, malignant, or, more scientifically, adynamic) type. The diseases to which I shall chiefly refer are fevers and erysipelas. It would be quite beyond the scope of this lecture to quote all the known instances in which wine was used therapeutically by our predecessors. I shall, therefore, confine myself to a few authors of special mark.

To begin with the father of physic, the great Hippocrates, we find that he discusses the use of wine in fevers, mentions the different kinds of wine, and when each is to be used. Although he does not detail as accurately as we could wish, the exact cases for the administration of wine, yet he tells us it is useful under particular circumstances, and, from his reference to the use of wine in anxiety, and under other circumstances, it is quite clear that he used wine in much the same way as we do at present—namely, to counteract debility. In the Aphorisms he warns us "to consider if the patient will support the diet," and cautions us to "purge sparingly in acute disease," showing that he quite understood the dangers of depletion.

Aretaeus tells us, in his chapter on "The Therapeutics of Acute Disease":—"But if converted into syncope, ... (the powers of life being loosened . . .) we must disregard the delirium—which he had previously stated contra-indicated stimulants—and be on our guard. . . . . . Then the only support is wine, to nourish quickly by its substance, and to penetrate everywhere, even to the extremities; to add tone to tone, to rouse the torpid spirit, warm that which is cold, brace what is relaxed, restrain those portions which are flowing and running outwards, ... most excellent to soothe the mind in delirium. Wine, when drunk, accomplishes all these good purposes, &c."[1]

Alexander Aphrodisiensis (quoted in the Sydenham Society's edition of "Paulus Ægineta") inquires how it is that wine which is of a hot nature proves useful in fever, and believes the wine acts by strengthening the powers of the system.[2]

Paulus Ægineta recommends a stimulant mixture containing wine, myrrh, ammonia, and aloes for the treatment of plague.[3]

Celsus III., 7.—Recommends wine and water alternately to prevent, and hot, undiluted wine to cure, plague.

Although there are many more examples to be found in the writings of the ancients of the use of wine in acute disease, yet, I think, I have given sufficient to show that wine was used thousands of years ago in the same way as it is at present—namely, when the cases required it, which, fortunately for our predecessors, was not so often as at present.

Passing from the ancient writings, we come to those of more modern times, and I shall confine myself to examples taken from the practice of the physicians of our own country, as it is they who are especially accused of depleting cases belonging to the class which we now stimulate. As we began the consideration of the use of stimulants in ancient medicine by the father of physic, so we shall begin this part of our investigation with examples from the practice of the father of English medicine, Thomas Sydenham, who was born in the year 1624, and flourished in the middle and towards the end of the 17th century. When writing of the fever of 1661 to 1664 he tells us, "Whenever I have to deal with a patient whose blood is of itself of a weak character (as it is for the most part with children), or else deficient in animal spirits (as it is with men in the decline of life, or youths who have long been invalids), I keep my fingers from the lancet. If I order venesection, the blood, weak enough without being diminished, would be rendered incompetent to the work of dispumation. Thence would arise the degeneration of its whole volume, whilst the death of the patient would probably come next. . . . In stating this, I am aware that there are patients upon whom rash blood-letting have been inflicted; that, by the help of proper cordials have out-lived the treatment," &c.[1]

From the foregoing statement, it is evident Sydenham was quite familiar with the cases of fever which could not bear depletion. In the following paragraph he mentions those that can bear depletion, and afterwards refers to a class of cases where depletion may be first used, and cordials afterwards.[2]

In the same chapter he again refers to the use of cordials and gives a caution—"As regards cordials, I am cautious in their exhibition," &c.

Again, in the same chapter, he directs (in a chest complication, in fever) "the patient to drink old Malaga wine, some Falernian, or Muscatell."[3]

Writing of pestilential fever of 1665, he mentions a case where malignant symptoms set in, and he ordered "strong almipharmics."[4]

When writing of erysipelas, we find him concluding with the following statement:—"I may also make a remark, by the way. Although the affections of which we are speaking, . . . easily give way to this treatment, and take themselves off after the repetition of a purge and a venesection, there are others of the same kind which must be treated in a manner wholly opposite."[5]

Farther on, in treating of a variety of erysipelas, he recommends wine and digestible animal food, and condemns refrigerants.[6]

I think I have thus shown you that the father of British medicine used stimulants in suitable cases, and frequently wine in his practice as such.

We now come to consider a few authors of the eighteenth century—

Huxham, about 1730, recommended the use of generous red wine in the treatment of erysipelas of a low type.

Heberden writing concerning erysipelas, and probably of cases which occurred in his practice about 1750, says:—"This distemper seems to partake of the nature of those which are called malignant, more than of the inflammatory, by which I mean, that in general it does not require nor bear much evacuation."[7]

We next come to Cullen, the greatest systematic writer on practice of physic of the last century. Cullen, writing of erysipelas, as he met with it, probably between the years 1760 and 1770, seems fully to appreciate the possibility of erysipelas assuming an adynamic type, such as Heluden had met with, he writes—"We have hitherto considered erysipelas as in a great measure of a phlegmonic nature;

and, agreeable to that opinion, we have proposed our method of cure. But it is probable than an erysipelas is sometimes attended with, or is a symptom of, a putrid fever; and in such cases the evacuations proposed above may be improper, . . . and the use of the Peruvian bark may be necessary; I cannot be explicit upon this subject, as such putrid cases have not come under my observation."[1]

From what Cullen says in other places of wine as a stimulant, it is pretty certain that if he had met with these cases of putrid erysipelas (as he called them), he would have employed wine in their treatment.

These instances of the treatment pursued by Huxham, Heberden, and Cullen, all bear upon the same point, and prove how exactly they practised according to the principles laid down by the best physicians of our own time.

In his chapter "On the method of cure in fevers," Cullen writes, "the most suitable is that which forms the indications of cure upon the view of obviating the tendency to death."[2]

In following out this plan, he tells us[3] (according as the circumstances of the fever shall admit)—

"1st.—To moderate the violence of the reaction.

"2nd.—To remove the causes, or obviate the effects of debility.

"3rd.—To obviate or avert the tendency of the fluids to putrefaction."

To fulfil the second of these indications, after mentioning the Peruvian bark, he says—"Another set of medicines to be employed for obviating debility and its effects, are direct stimulants. These, in some measure, increase the tone of the moving fibres, but they are different from the tonics, as more directly exciting, and increasing the action of the heart and arteries."[4]

"What are the stimulants that may be most properly employed, I am uncertain, as the use of them in this age has been rare; but I am disposed to believe that of all kinds wine is the best.

"Wine has the advantage of being grateful to the palate and stomach, and of having its stimulant parts so much diluted, that it can conveniently be given in small doses; so that it may be employed with sufficient caution: but it is of little service unless taken pretty largely."[5]

A more concise and correct account of why wine is of so much value as a stimulant is not to be met with in medical literature. It would be well for those who tell us that Dr. Todd originated the fashion of using wine in disease, if they would go a little further back and study the writings of the physicians of the last century.

Cullen further tells us that "wine has an action analogous to that of opium and some other narcotic medicines. It may indeed be said, we can distinctly mark its stimulating power only, which renders its effects in the phrenitic delirium manifestly hurtful, and in mild delirium, depending on debility, as remarkably useful."[6]

Cullen also recommends wine in malignant small-pox, "commonly proper to give wine very freely."[7]

In the prevention of plague:—"Some means may be employed for strengthening the bodies of men, and thereby to enable them to resist contagion. For this purpose it is probable that the moderate use of wine, or spirituous liquor, may have a good effect."[8]

In the foregoing quotations and remarks, I believe I have not failed to prove, that wine has been used as a stimulant through a long series of years, and I have, I think, returned a decided negative answer to the question—Is the administration of wine in medicine a mere fashion? I have proved the falsity of the charge; that our great predecessors in the healing art had no idea how to use wine, have shown you how closely we follow the principles for practice laid down by our great masters of various ages, and lastly, have pointed out to you the means of confuting the great *stock arguments* of the most pernicious, spurious, and ignorant cavillers at the use of alcoholic stimulants in medical practice. In our next lecture I shall point out some more of the errors of these mischievous allies of teetotal bigots, and the worst enemies to the progress of temperate habits among the mass of the public. To-morrow we shall enter more minutely upon the physiological action, the scientific employment of alcoholic stimulants in disease, and the when, where, and how they are to be used with benefit to our patients.

Original Communications.

HOW SHALL WE MAKE OUR DAILY EXPERIENCE ADVANCE SCIENCE?

By THOMAS KING CHAMBERS, M.D., F.R.C.P.Lond.

(Read at the Meeting of the British Medical Association at Oxford, August, 1868.)

Our presence here in Oxford shows that we are all anxious to aid the progress of our common art and science. But many of us—most of us—are at the same time willing to confess that we do not know very well how to set about it. Our country cannot spare us, even if we ourselves wished to devote our lives to the mere cultivation of knowledge; and we are tempted to despair of seeing anything less than a complete devotion produce fruit. Are we justified in this despair? I think not. I think it not at all impossible to extract, from the gigantic waste of our daily routine of business, constituents of truth as important as any dug fresh from the mine of devised experiment. I believe we shall, like our manufacturing industry, advance chiefly now by utilising our waste products.

Let us begin first by saving them, instead of letting them run off into the sewers of forgetfulness. I think it is the duty of a practitioner of medicine to take notes of every case that comes under his charge. It is especially those which superficially appear commonplace and repetitions of one another that need to be thus recorded. Rarities are common enough, and are enshrined by wholesale in the storehouses of our periodical literature; but when one comes to look for accounts illustrative of any point about the daily events of life, they are wanting. Let a man, for example, ask of those who have been giving aloës all their lives, for any evidence of the truth of the statement, which we have been repeating after Fallopius for 250 years, that the drug causes hæmorrhoids and morbid uterine hæmorrhage—in what cases it cures them, and in what it makes them worse—let him ask how often it elicits solid, how often liquid stools—in what cases the former, in what the latter—and I fear he will get none but conjectural answers. Or let him ask those who are daily administering some expectorant, whether the expectoration is increased or diminished under its use, and he will hear a strange absence of consent in the reply. Let him ask how often ascarides produce symptoms, and in how many persons they are found without symptoms—whether bronchial catarrh most frequently precedes or follows measles—what is the period of latency of gonorrhœa—and in short, almost any question about almost any common illness, and he will have it answered much more rarely from personal observation than if he inquired about some strange complication, of which not five instances are seen by a man in his lifetime. Yet it is the common diseases which are of real importance for us to lighten and shorten. Moreover, it is in common diseases only that we can learn the therapeutical value of drugs, for it is in these cases only that we know the natural course of the malady, and can judge how far it is modified by our means.

Medical men are often deterred from keeping a systematic record of their private practice by the idea that to do so necessarily involves a considerable expenditure of time. I doubt the fact. Certainly the careful annotator is longer over his first visit to a patient, than is a hurried prescriber; but then subsequent visits are much shortened, for the refreshing of the memory by a repetition of questions is avoided. But still the time thus spent is an important part of the question, and it is very desirable to reduce it to a minimum by mechanical contrivances. The plan I myself adopt is as follows:—I write all my prescriptions and papers of advice in a copying-book, which preserves a duplicate of them by means of transfer paper (Delarue's Copying-book); and at the back of this transcript I write, usually with the patient before me, always before I attend to the next case, the history, so far at least as to explain my reasons for the advice, before I go on to the next page. The periodical indexing of these pages is an easy job for an hour of weariness; and the whole time consumed is so crumbled up that it is never missed, and neither business nor amusement can complain of the robbery.

---

[2] Op. Cit. Vol. I., p. 159 and seq. [3] Ib. Vol. II., p. 160.

[4] Ib. Vol. I., p. 222. [5] Ib. Vol. I., p. 223. [6] Ib. Vol. I., p. 224.

[7] Ib. Vol. II., p. 195. [8] Ib. Vol. II., p. 249, and et seq.

Some people suppose they can make their notes of the day's work more fully and scientifically when it is over, and they quiet in their studies. I do not like the plan so well. For one thing it interferes with the relaxation needful to keep the mind healthy and broad. That time belongs to rest, and should not be wasted on labour. An instinctive feeling of the truth of this causes a duty which is put off to such an opportunity to be put off often still further, often altogether. Again, unless an immediate note be made, the new and the strange in the day's experience are stamped in the mind deeper than the commonplace, and they are apt to take up more than their fair share of room in the diary; while personal friendship, the social standing of the patient, and other considerations, will sometimes blot out, sometimes unduly brighten our recollections of the case.

What should be recorded? Not everything of course, or there will be a want of perspective in our sketch. The best rule is to note first the prominent important features in the case in our technical eyes, those features which have guided us in our treatment, and which distinguish it from others. Other features may follow, receding from the history in inverse proportion to their prominence. A separate paragraph at the end may contain the symptoms which appear the chief to the patient, for the purpose of allusion in a future visit.

What are the uses of these notes? They serve as corrections to our memories—they make available to the increase of real knowledge that which is otherwise just as likely as not to lead to imperfect, and therefore false, knowledge. They turn a stumbling-block into a stepping-stone. What a satisfaction, when a new question is raised in our own minds by some chance patient, or suggested by a colleague, to be able to answer "*littera scripta manet*," here is the contemporary evidence of the fact! How pleasant in an hour of leisure to live over again one's days of joyful labour! But above all, how invigorating to be able to contribute true bricks to the palace of knowledge which we are uniting to build up!

One of the most important matters for inquiry in the present day is the action of drugs on the human body. There are questions concerning these reagents which practitioners only have the opportunity of testing, and in no other way can they do it so satisfactory as by daily notes, which can with ease at any time be reduced to a tabular form.

This brings me to another part of my subject, namely, the administration of medicines. I wish to offer a few suggestions which may tend to make this daily business of ours more available in increasing therapeutical science. 1. Let us aim at giving only *one drug at a time*. I do not say this is always possible; but at all events let us keep the desire in our minds, and reckon a prescription good in an inverse ratio to the number of ingredients. This simplicity conduces not only to the good of science, but of our individual patients, for it soon makes us much more ready at suiting the special remedy to the special case. 2. It is important when we change our treatment to allow a certain sufficient interval, different in different instances, between leaving off one medicine and beginning another. The experiments of Böcker and others have shown us, first an action of the drug lasting after its apparent disappearance from the body, and, secondly, a reaction of the system opposite to, though weaker than, the original action. Advantage will accrue to the patient, as well as to science; often from this rule, too, less medicine will be needed. For instance, hyoscyamus given for hypochondriasis or mental depression may be left off almost directly it has begun to produce its beneficial effects, and those beneficial effects will still go on towards restored health. Hydrochlorate of strychnia will continue to invigorate the peristaltic motions of the stomach and intestines, so as to produce steady digestion and evacuation for days after such a soluble salt must have passed away. 3. It is advisable for each observer to have as short a pharmacopœia as possible. The best workmen use the fewest tools—aye, and those who use the fewest tools become the best workmen. They become more adroit with them, know them better, and are able to instruct others in their employment. 4. The union and co-operation together of those who are working at the same subject is of incalculable value. Incalculable—because you have not tried it. The skeleton of the machinery exists in the British Medical Association. Why should not each branch or group of branches take up a drug and let us know after two or three years their experience of its action?

PRACTICAL SCHEMES FOR EXTENDING THE CONTAGIOUS DISEASES ACT TO THE CIVIL POPULATION.

By HENRY W. WILLIAMS, M.D., C.M.

Public immorality has obtained such magnitude, especially of later years, that it is quite time the State adopted some means to bring it under control—a very difficult matter, indeed, in this country; for to do so the Government must more or less sanction prostitution.

It must be done in some manner or other, and that very shortly, too—

First. To prevent public decency from being outraged to too great an extent.

Secondly. To ameliorate, cut short, and finally eradicate, if possible, primary disease amongst the original offenders.

Thirdly. To ward off and counteract the baneful effects of a vicious life, as so frequently developed in the innocent offspring of those who have contracted syphilis and been imperfectly cured.

Licensing houses in England for prostitution is repugnant, more or less, to the feelings of all of us; how much more horrible does the idea seem of licensing each individual woman. Bad as it is, I can see no other way of truly meeting the social evil, and bringing it under thorough and efficient control, than by licensing, in the first place, individual women with either an ordinary or a special license; secondly, to license houses, such houses to include regular brothels, night-houses, also receiving-houses, coffee-houses, hotels (known as houses of resort for prostitutes), tea-gardens, music-halls, &c.

With regard to the ordinary and special license, I mean the *first* is for women living in houses with two or more inmates; the *second* for women living in private rooms. Every woman who is known to live totally or partially by prostitution should be registered, numbered, and licensed; and if to live in a house with others, she should pay for such license five shillings, which would stand good for one year in any part of the United Kingdom. If a woman requires a license as a courtesan to live singly in apartments where there are no others but herself in the house (kept women, ballet-girls, shop-girls, &c., are included under this head), such a license to be considered special, and to cost five-and-twenty shillings. Of course there will be numbers of girls who will evade the law, and partially practice prostitution without a license. If such infect men, and are found unregistered, they must be punished.

Every brothel with two inmates should pay five pounds a-year for a license, such license to allow the keeper thereof to sell wine and spirits (to be drank on the premises), and the women in such a house to be inspected weekly by the surgeon, for which five shillings for each visit, including such inspection, would be charged in addition to the license; for every additional woman over two, a shilling extra for inspection would be charged. All other houses enumerated above, not regular dwellings for courtesans, but yet resorted to by them for accommodation, to be taxed according to their rental. The proceeds arising from the licenses and inspections to pay the expenses of examination, and the surplus to be devoted to the erection and maintenance of a National Lock Hospital and Magdalen Asylum in the metropolis, with branches in the various towns of the United Kingdom ; so that those courtesans who are diseased may receive board and lodging, with medical treatment, free of expense when ill, and, at the same time, the Magdalen affords those who may repent of their vicious course of life, an opportunity of reformation, inasmuch as they can enter free either after illness or any time they like, and be kept until drafted into various situations or sent to the colonies, where old habits forsaken, the past forgotten, they may lead not only virtuous lives but become, mayhap, in time, good wives, happy mothers, christian women, and useful members of society, the consequence of their being helped out of the mire by the kind hand of charity when they stood the most in need of it, having a free place of refuge to fly to when prompted by their good angel to forsake their wicked manner of living and to try and do well once again. I feel convinced if the hand of charity were offered more frequently than it is to our fallen sisters, a great many more might be reclaimed. Only give them the opportunity of getting an honest living, and there are very many who would gladly avail themselves of the offer ; and yet, on the other hand, there are numbers who would not, nay, could not, be quiet and decent if they were paid for it.

At the same time that I am advocating the licensing of courtesans, I would deal most severely with that class of persons, both male and female, known as Procurers and Procuresses, villains of the deepest dye, who undertake to supply the market of prostitution by entrapping young girls and systematically causing their ruin. Transportation for life would be none too great a punishment for such sinners, who, for the sake of gain, lead a maiden (very often under the influence of alcohol, caused by their infernal means,) to the couch of seduction, thus giving them the first plunge into a career of iniquity, introducing them to a vicious course of life, in fact, teaching them—compelling them, to sin, and glossing over their atrocious act by pointing out the freedom of life which they, poor creatures, will for the future enjoy, showing forth all the gaieties and pleasures of this world, and using many other diabolical means to ruin innocence, accomplish their vile ends, and justify themselves in the eyes of their deluded and unfortunate victims.

If a girl, of her own free will, chooses to sin and lead a life of riot and dissipation, and others who through misplaced affection commit their first error by losing their virtue, and then follow up a gay life, why, no one is to blame save themselves. Courtesans have existed from time immemorial, and one may depend upon it they will continue to do so as long as the world lasts in spite of Church endeavours to reform them, or State attempts to suppress them. So, of two evils choose the least, and, if we cannot put down prostitution, we can, at any rate, bring it under surveillance and official control with the greatest benefit not only to the demi-monde alone, but to society at large. Licensing and inspection would have to be carried out by a body of medical men appointed especially for the purpose, consisting of—Divisional Surgeons, Superintendent Surgeons, Inspecting Surgeons, Chief Inspecting Surgeons, the Inspecting-Surgeon-in-Chief.

The Divisional, Superintendent, and Inspecting Surgeons would be appointed according to the number of houses, and a Chief-Inspecting Surgeon would be allowed for England, Wales, Scotland, and Ireland respectively, the whole to be under the immediate and absolute control of the Inspecting Surgeon-in-Chief. To the best of my knowledge, upon the authority of Dr. Charles Drysdale, there are 10,000 courtesans in London, say 8000 are regular *bona fide* prostitutes, the remaining 2000, whom we will style "irregulars," consist of, we will suppose, kept-women, shop-girls, &c., living for the most part by themselves, the 8000 living in regular brothels, and so allowing four to a house on the average, gives the number of houses as 2000 ; each of which houses would have to be inspected weekly, and licensed yearly at the rate of £7 each, which gives per annum £14,000

Allowing seven shillings a-week for examining the inmates in each house, that would bring in annually the sum of	36,500
Then the 8000 ordinary licenses would average per annum	2,000
Then the 2000 irregulars with special licenses would amount yearly to	2,500
Irregular courtesans would be examined at the consulting-rooms of the Divisional Surgeon at the rate of 1s. 6d. a-week on each examination. Such brings in yearly	7,800
Such women would have to come to be examined at appointed times, or they would be charged more than the 1s. 6d. if they came out of hours ; or if they were visited at their own homes, such extra fee to be considered the perquisite of the Divisional Surgeon.	
Coffee-houses and public-houses, &c., used for immoral purposes to pay a shilling in the pound on their rental. Now there are 500 in London, I believe, known to the police, and these would bring in (extra per year)	2,000
Thus giving for London only for the year a total of	£64,800

Say a Surgeon could inspect fifty houses a week, and examine the inmates, that would allow him ten a day, and leave Saturdays for making up books and examining irregulars at his consulting-rooms.

Forty Divisional Surgeons would thus be required for London, with salaries varying from £400 to £500 per annum, allowance (extra) being made for travelling expenses, rent of rooms, and use of instruments, &c.

Say that each Divisional Surgeon, on the average, had a salary amounting to £500 a-year, that would make a yearly total for the forty of	£20,000
Every ten Divisional Surgeons to have a Superintendent at £500 per annum, with £100 for travelling expenses, &c., equals for London, yearly, ...	2,400
Every forty Surgeons to have an Inspecting Surgeon at £600 a-year, with £200 for travelling expenses, &c., gives for the year	800

Thus the London inspecting expenses would be as follows :—

40 Divisional Surgeons' incomes, ...	£20,000
4 Superintendent Surgeons' incomes, ...	2,400
1 Inspecting Surgeon's income, ...	800
For stationery, licenses, and stamps, ...	2,600
Making the total amount	£25,800

Thus, after paying all expenses for examination, &c., there would be a surplus of £39,000 a-year, which would go a long way towards supporting a National Lock Hospital and Magdalen Asylum.

The four chief Inspecting Surgeons to have a yearly salary of £900, with £300 for travelling expenses, &c. The Inspecting Surgeon-in-Chief to have, yearly, £1500, with £500 for expenses. Surgeons of all grades to be bound down not to practise to the detriment of their daily occupation, under penalty of fine. Seeing patients at their own residences after the duties of the day, or even visiting such at their own houses at that time, would be sanctioned, provided it did not interfere with their Government work.

Women found guilty of prostitution, without a license, to be fined or imprisoned, according to the frequency or gravity of the case.

All houses to be open at any hour of the day or night to the Surgeons of the various grades.

Divisional Surgeons to take the money for the weekly examinations at the same time that such examination is made—the number of the house (by license) and the sum to be entered in a book kept for the purpose by him.

The keeper of any house guilty of misconduct in keeping such house, say, permitting robbery or disgraceful riots to take place in such house, to be fined, say twice, and then have his or her license suspended as long as may be thought fit by the Inspecting Surgeon-in-Chief.

All monies for licenses to be paid to the Superintendent Surgeons, and the monies received by them, and those received by the Divisional Surgeons to be paid monthly to the Inspecting Surgeons, who in their turn pay it to the Chief Inspecting Surgeons. All books and accounts to be open to inspection any time during the day by the Inspecting Surgeon-in-Chief.

In cases of illness on the part of any of the surgeons, he may appoint a deputy, subject to the approval of the Inspecting Surgeon-in-Chief.

Three weeks holiday to be allowed during the year to Divisional Surgeons, but they must find a deputy and pay him out of his salary, as his pay goes on all the time he is away from duty, either for pleasure or on account of sickness. In case of any violence offered to the Divisional Surgeon, he may call in the Police to work with him, and in case of any prostitute refusing to be inspected, she can be given in charge there and then. Clerks to make up books can be kept by any of the surgeons, provided such pay the incurred expense.

Any surgeon found guilty of immoral conduct, appropriating monies to his own use, making false entries, or otherwise breaking his trust with Government, to be reprimanded, suspended, or cashiered, and then dealt with as the civil law might determine, according to the nature of the charge proved against him.

Divisional and Superintendent Surgeons to be Honorary Surgeons to the Lock Hospital.

Inspecting and Chief Inspecting Surgeons to be Governors of the Magdalen Asylum.

Surgeons of every grade to have access to the Lock Hospital and Magdalen Asylum any time during lawful hours.

ON THE NATURE OF THE PHENOMENA OF PAROXYSM AND INTERMISSION.

By H. FREKE, A.B., M.B., M.D., T.C.D., M.R.I.A.,

FELLOW OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO DR. STEEVENS' HOSPITAL, DUBLIN; LECTURER ON THE PRACTICE OF PHYSIC AND ON CLINICAL MEDICINE IN STEEVENS' HOSPITAL SCHOOL OF MEDICINE, ETC.

It has ever been the opinion of observing and reflecting physicians, that among the phenomena of disease most involved in obscurity and presenting greatest difficulty of interpretation, are to be placed what are known as periodic and paroxysmal phenomena.

The convulsions of epilepsy, the intermissions of ague, the remissions and spontaneous subsidence of fever, &c., afford examples of the class of phenomena referred to; and the most eminent authorities on pathological questions have long been of opinion that their correct interpretation was among the difficult problems of medicine.

One of the greatest ornaments of the medical profession in this or any country—namely, Dr. Stokes of this city, who, as an accurate interpreter of pathological phenomena, is second to no physician existing, speaks in his able lectures on fever, in 1854, of "this mysterious law of periodicity."

Other great authorities might be quoted to the same effect, but it is needless, inasmuch as the difficulty is universally admitted.

The subject is one that had for some time occupied my mind, and in the years 1851-52 and '53, when contemplating it exclusively in its relation to fever, I bestowed on it much thought, and at length satisfied myself that I had arrived at its correct solution, which I published in THE DUBLIN MEDICAL PRESS, 25th of May, 1853. That solution is, I believe, now considered by many to be correct.

The purport of what I advanced, may be briefly epitomized thus, viz.:—

1st. That the time during which any of our organic tissues, say a ganglionic nerve centre for example, is capable of manifesting its function must of necessity be limited, that is to say, no such tissue can go working *incessantly*, or beyond *some* definite period of time.

2nd. When that limit has been reached, or in other words, when that ganglionic centre has completely exhausted its function or expended its entire nerve force, it is impossible that a similar function or a similar expenditure of nerve force can take place, till after a period of pause, intermission, or rest; during which pause, intermission, or rest, a new ganglionic centre must be developed by the process of nutrition in order to admit of a repetition of that function; namely, a second expenditure of nerve force. And consequently,

3rd. That after the complete exhaustion of its function, or complete expenditure of its nerve force by any ganglionic centre, there must be a period of pause, intermission, or rest, during which a new ganglionic centre is being developed by the process of nutrition or renewal, which new ganglionic centre, when completely developed by that process, will be capable of re-manifesting its function; that is, will be competent to redevelop nerve force.

The same is equally true of muscles and of animal organic tissues universally. Such is the nature of all intermitting paroxysmal phenomena.

To illustrate these statements, take, as an example of a paroxysmal and intermitting disease, that terrible affliction known as epilepsy. Epilepsy is a well-marked paroxysmal intermitting disease. In each paroxysm of epilepsy it is well known there is an active development of function, or expenditure of nerve force, by the motor nerve centres of the medulla oblongata and spinal cord.

Now, in such paroxysm we see that so soon as those motor nerve centres of the medulla and cord have completely expended their function, or exhausted their nerve force in producing convulsions, there is a pause, intermission, or interval of rest before a second fit or paroxysm occurs.

Such is what we see to take place in epilepsy. Such, I submit, is what must take place in all paroxysmal diseases. After the expenditure of function in paroxysm there must, in all instances, be an interval of rest before the occurrence of a second paroxysm, and this interval of rest is what constitutes the intermission.

And why the necessity for this interval of rest?

For this reason—it is during, and only during, this intermission, or interval of rest, that a new ganglionic centre is being developed by the process of nutrition. When such new ganglionic centre has been developed, and not till then, it may give rise to a new display of function, a new expenditure of nerve force, in a word, to a second fit, or paroxysm of the disease.

I would submit that nothing of this nature was recognised as the true explanation of the phenomena of paroxysm and intermission till some years subsequently to May, 1853.

I shall now submit the terms in which I expressed those views in May, 1853, and would ask the reader to observe how closely I have adhered in the foregoing *resumé* to the language originally employed.

Having dwelt at some length on the well-known and long established physiological fact that our organic tissues, such as nerves, muscles, &c., while in the act of giving manifestation to their respective physiological functions, themselves undergo the process of disintegration, or what is termed retrograde metamorphosis.

I thus observe[1] :—"An organised structure adapted for developing physiological phenomena, is *competent* to give development to the phenomena in question (be their nature what it may) only to a *limited or definite extent.* No individual organised structure, in other words, whatever be its nature, or whatever be the nature of the phenomena it is specially designed to develop, could, by possibility, develop those phenomena to an *unlimited or indefinite extent.* The same proposition may be otherwise expressed thus—viz., the limit or extent to which any individual organised structure is capable of developing its physiological function, is strictly defined and cannot be exceeded."

Applying this observation to nerves, muscles, &c., I remark :—"Suspend the process of 'nutrition' in any one of those structures, and what is the result ? The result is, that the function of that structure must soon be suspended. Now what, in physiological language, is the process of 'nutrition ?' It is nothing more or less than the process of *re*-generation or *renewal.* A continuance, then, for an *indefinite* period, of the process of 'nutrition' in any individual structure, is, in physiological language, nothing more or less than a *re*-generation or *renewal* of that individual structure *an indefinite number of times.* Consequently, as is obvious, when the function of any organised structure, such as muscular fibre, &c., &c., *is* developed to an *indefinite extent,* it is not the *same individual tissue* which in that case has been *exclusively* employed in giving development to that function ; but, on the contrary, that function has been developed by a *succession* of *renewed* or *re*-generated tissues."

I then went, at some length, into detail on the application of these observations both to muscular fibre and to the ganglionic centres of nerves.

In reference to their application to muscles I observe :—"What I mean to express by the terms 'during a given or definite period of time,' may require to be somewhat further explained. What I am desirous of conveying is this : by the words given or defined, as applied to the period of time during which any muscle is in physiological action I wish to express—*that period of time during which any individual muscle is undergoing the process of de-generation.* I shall endeavour to render my meaning more intelligible. By the repeated exercise of his muscles, an indefinite number of times, after definite intervals of rest, the same individual may develop an indefinite amount of muscular force—may, for example, raise an indefinite weight, or draw an indefinite load. During the course of a *year,* for instance, I could move a much greater weight than an elephant could move in an *hour.* True : but mark this distinctly, it is not the same muscular fibres which in this instance have developed all the muscular force which has been expended by me during that year ; but, on the contrary, a succession of muscles, altogether distinct from each other. For the first fibres so employed have long since ceased to exist, having, during the discharge of their function, undergone the process of *de*-generation, and have been eventually removed from the system to give place to a new set of fibres. This new set in their turn have undergone the same process of *de*-generation, giving place to a third set, &c.

In this quotation, I would solicit the reader's special attention to the words "given or defined period of time," and to the words, "after definite intervals of rest."

These are the two topics of importance in relation to the phenomena of paroxysm and intermission.

Thus, in the case of an epileptic paroxysm, the "given or definite period of time" is the period of time during which it is possible for that paroxysm to last. At the expiration of this period of time there of necessity comes a definite interval of rest, which interval of rest constitutes the intermission.

Such definite interval of rest may be succeeded by a second paroxysm, and so on indefinitely. Paroxysms which can last but for a definite period of time must be succeeded by definite intervals of rest or intermission. Such is the nature of the phenomena of paroxysm and intermission. In a word, as in each fit of epilepsy, so in *all* paroxysms, there can be an expenditure of a definite, and only a definite, amount of either muscular or of nervous force, but the fits of epilepsy may be repeated or renewed an indefinite number of times provided, and only provided, there be definite intervals of rest or intermissions between each such repetition of the fit.

During the intermission or interval of rest new tissues are formed which may give rise to a renewal of the fit, and so on indefinitely.

In continuation of this subject I further observe :—"Let us suppose one single individual muscular fibre detached from all others, and contemplate that fibre in relation to the following question—viz., as to the measure of the period of time during which that individual fibre can discharge its physiological function. That period of time is measured or defined by what I have termed the *de*-generation of that individual fibre. For that muscular fibre, while in the act of discharging its function, is itself undergoing a process which must eventuate in a total inability on the part of the same individual fibre, to give further development to muscular force. When that process (viz., of degeneration) has been completed, the individual fibre under consideration is degenerated, and in its degenerated condition it is incompetent to develop muscular force. Consequently, for the further development of muscular force, there is required a *re*-generation of muscle ; or, in other words, the formation of a new and altogether distinct muscular fibre. Hence it is obvious that the process of *de*-generation puts a limit to the time during which any individual muscular fibre is competent to develop muscular force. Now, it is obvious that the duration of that time will be longer or shorter according to the degree of activity with which the process of degeneration takes place in that fibre ; or which amounts to the same thing, according to the degree of activity with which that fibre discharges its physiological function."

I would submit that the foregoing quotations must, at once and without effort, be intelligible to the most ordinary and commonplace understanding.

There can be no difficulty in understanding that if, at any time, a single individual muscle or a single individual ganglionic nervous centre be *worn out* in the discharge of its function, there must be a period of pause for the growth of a new muscle or new nerve centre before the functions belonging to a new muscle or nerve centre can be discharged, and until such new growth has taken place there will be the intermission.

On the same subject I further observe :—"What I am desirous, then, of conveying by the terms, 'in a given or definite period of time,' as applied to the time during which a muscle is discharging its function is this—viz., the period of time during which the *de*-generation of any individual fasciculus of muscular fibres (irrespective of, and in contradistinction to, *new* or *re*-generated fasciculi) is in actual progress, or in the act of taking place."

On the application of the foregoing observations to ganglionic nervous centres, I thus observed :—"Now what is true of *all* organised structures, is true of *the ganglionic system of nerves,* and it is upon that account I have dwelt thus long upon this topic. The reader will have the goodness to reflect upon the bearing of this fact—viz., a *ganglion* is *capable* of developing but a *limited* amount of nervous influence or force. Let me be distinctly understood. No *single individual* ganglion (irrespective of *renewed* or *re*-generated ganglia) could, by possibility, give development to more than some *fixed* and *definite* amount of nervous influence or force."

Adding, on the same subject :—"The ganglionic system of nerves *are capable* of developing only *a given or definite amount* of nervous influence or force *during a given or definite period of time*."

---

[1] Dublin Medical Press, 25th May, 1853, Vol. XXIX, pp. 322-23.

And further on, observing in relation to the ganglionic nerves:—"They, too, as I regard it, can develop but a limited amount of nervous influence or force during the definite period of time I refer to; that is, during the period of time which is defined by the *de*-generation of individual ganglia, irrespective of *new* or *re*-generated ganglia."

And adding—"Hence the process of *de*-generation (as in the case of an individual muscle) puts a limit to the time during which any individual ganglion can develop nervous influence or force. Hence, too, it is obvious (in like manner as in the case of muscular fibre) that the duration of that time will be longer or shorter, according to the degree of activity with which the process of degeneration takes place in that ganglion; or which amounts to the same thing, according to the degree of activity with which that ganglion has discharged its physiological function of developing nervous influence or force."

Thus, then, it is obvious that when once any given ganglionic centre has expended, or exhausted, its entire nerve force, say in the production of convulsions, there must be a pause, intermission, or rest, before a similar expenditure of nervous force can take place—namely, until a new ganglionic centre has been developed by the process of nutrition.

I might introduce many more quotations to the same effect, but it is needless. I may, however, be permitted to add, that throughout the papers referred to, which extended over a period of upwards of two years, I had gone at great length into the subject of nutrition. I had remarked extensively on the nature of that process, how it took place, and what it accomplished. I had pointed out at considerable length how, after the complete expenditure of muscular force by a muscle, or of nervous force by a ganglionic centre, a new muscle, or a new ganglionic centre must be developed by the nutritive process. And I had further extensively entered into detail as to *the manner in which* those results were brought about by that process. It is unnecessary to add more on this subject, but what I desire to impress on the reader is this—namely, that in 1853 I pointed out in as simple, clear, and intelligible language as could be employed for that purpose, the following physiological principles, viz.:—

That in the discharge or performance of their respective physiological functions, by muscular fibre, by ganglionic nerve centres, and by animal organic tissues universally, "time defined" manifestations of function must necessarily be followed by "definite intervals of rest," during which rest a re-development, or renewal of the tissue employed, must be effected by the process of nutrition before a *repetition* of that function can take place.

EPILEPSY.

CASE OF SPINAL ORIGIN: OBSERVATIONS UPON ITS PATHOLOGY AND TREATMENT: BROMIDE OF POTASSIUM AND BICHLORIDE OF MERCURY.

By P. C. LITTLE, F.R.C.S.I., &c.

In continuation of my remarks upon epilepsy in Vol. III., No. 25, of your journal, I beg to contribute the following case of spinal origin, which manifests some remarkable epileptic phenomena not noticed in my former paper.

June 20, 1867.—A. B., aged 23, a professional gentleman of ability and studious disposition, consulted me for those conditions:—A constant irritation and painful weariness at pit of stomach, occasionally relieved by the falling down, as it were, of something from the chest, followed by a tickling sensation about the stomach; has "always a wish to breathe," much difficulty in that act, mitigated by bending forward; habitual sighing and yawning; pain down the spine and around the lions; great distress in sitting erect for any considerable time; giddiness on prolonged mental or physical exertion; noise in the head, flushing of face, congestion of hands, muscular tremors, irritability of mind; frequently dislike of conversation or company; insatiable appetite, unrefreshing sleep, hideous dreams, drowsiness and increased discomfort at noon.

His features appear pretty healthy; eyes dull, watery; pupils slightly contracted, conjunctivæ bloodshot; gait inclined forward; hands blue, cold; pulse 78, small, nervous. The chest presents a striking appearance. It is very lean, flat anteriorily, contracted, and almost of the same circumference from clavicles to false ribs. Below the latter is a notable dilatation reaching to the hips. Respiration, 14 per minute, is diaphragmatic and abdominal; inspiration prolonged and laborious, expiration short and bellows-like. The thoracic respiratory muscles are almost quiescent and poorly developed, excepting serratus magnus; those of the abdomen are active, large, and well-defined. Support around the diaphragm affords comfort, and facilitates breathing. The heart and lungs are healthy, the vesicular murmur feeble. The spine is red, congested, and hot; deep pressure upon either side of seventh and eighth dorsal vertebræ creates much pain.

The patient dates his malady ten years back, when he over-heated himself at play, and caught cold. Vertigo and uneasiness about the stomach thenceforth became the prominent symptoms. About two years passed, he fell in a fit in the street, lost consciousness, was convulsed, foamed at the mouth, and so continued for nearly a quarter of an hour. Five weeks ago, he sustained "a fearful nervous shock in the back," so enervating that he was obliged to keep his bed for several days, has been since incapacitated for mental labour, and dreads every moment a similar visitation. He lives regularly, but in earlier days applied himself too constantly to literary pursuits. One of his parents inherits consumption; the other, in years gone by, was subject to fits, and has yet many epileptic conditions.

The following was my general line of treatment:—I prescribed bromide of potassium, in doses of ʒss. to ʒi. *ter in die*, in a tonic mixture; counter-irritation to the spine, by vessicating collodion; a wide belt around lower ribs, as a support to the diaphragm; bland, nourishing food; gentle outdoor exercise, and quiet of mind.

Under this course he improved for the first fortnight, after which he failed so much in strength and nervous energy, appetite and taste for food, that, at the end of the month, he thought himself "worse than ever." I therefore discontinued the potash, and gave, instead, bichloride of mercury (1-12th gr. *ter in die*) in bark. By gentle perseverance in this alterative and tonic treatment for about three weeks, his distressing symptoms gradually disappeared; and by a change of air and scene, a short sojourn at a distant seaside, his long-impaired health was re-established.

This case manifests important epileptic symptoms, especially affecting the respiratory functions. Pulmonary disturbance is characteristic of this disease, and is best exemplified in a typical case. A fit is ushered in with a strong contraction of respiratory muscles, "the epileptic cry," closure of the glottis, and cessation of breathing. Convulsive and irregular pulmonic efforts follow, which end in slow, laborious breathing, and recovery. In the interparoxysmal periods the respiration is frequently obstructed, inspiration usually difficult. Those abnormal conditions find a general explanation in widely-accepted principles regarding the medulla oblongata.

The co-relation of this structure with other cerebro-spinal centres is thus laconically described by Flourens:—"The cerebrum feels and wills, the medulla oblongata executes, and the cerebellum co-ordinates." The oblong medulla is, therefore, the starting-point of all convulsive movements of epilepsy,[1] it also embraces the respiratory tract,[2] is the centre of the reflex motor system,[3] and I am tempted to add, appears to be the organ (if there be any special one) through which the mind directly communicates with matter. Speculators upon the latter intricate question may find that, the medulla oblongata has stronger claims to this eminent position than either the heart, cerebral hemispheres, or pineal gland. Extirpate the brain, spinal cord, or heart, and may not phenomena of life still be produced? Isolate from other nervous centres the medulla oblongata—nay, injure slightly its lethal point, *calamus scriptorius*, and will not all vitality at once cease? The part which the oblong medulla acts in the production of epilepsy seems to be clearly, though indirectly, demonstrated by one of our learned transatlantic brethren. In 1862, Professor Josh. Jones, University of Nashville, U.S., wishing to ascertain the therapeutic action of prussic acid, performed upon alligators very many experiments, which conclusively proved that the poison only produces its fatal effects when carried by absorption or directly applied to the medulla oblongata, and that *the first and most marked phenomena (the spasms) and the respiratory disturbance which rapidly extinguish life are the immediate effects of the poison upon the medulla oblongata.*[1]

---

[1] Admirably elucidated by Van der Kölk in his work on "The Spinal Cord, Medulla Oblongata, and on Epilepsy."

[2] Sir Charles Bell.

[3] Dr. Marshall Hall on "The Nervous System."

It is chiefly in its relation to respiration that we have at present to regard this structure. To it is specially ascribed inspiration, while to a yet undetermined segment of the spinal cord expiration is referred. Analogy supports this view. Observe the compensating organic and functional forces of the system, and the character of respiration, which in a manner resembles the alternate rising and falling of the scales of a balance. The muscular mechanism by which this twofold movement is carried on is so directly controlled by the medulla oblongata that, excitement of the latter, whether arising from a nervous centre, or periphery, increases the respiratory function, and is reflected in spasmodic or convulsive actions of the muscles of respiration, which destroys their harmony of action. Viewing respiration as an automatic movement, its regularity depends proximately upon the faithful discharge by the inspiratory and expiratory organs of their reciprocal functions. In epilepsy, the effects of the undue action of the medulla oblongata are more strongly marked in the inspiratory apparatus, which is more directly opposed by a counteracting force than the expiratory. This force originates in the anatomical and physiological relations of the thoracic respiratory muscles. For instance, the internal intercostals which proceed upwards and inwards act in pulling down the ribs, and so assist in expiration, in opposition to external intercostals, which go downwards and outwards, and elevate the ribs in inspiration. The result of such immediate antagonism is a comparatively fixed state of the thorax. On the other hand, where such counteracting forces are less evenly balanced, or where the usual action of a certain set of muscles is less disturbed, their function is more natural, as, I think, is exemplified in this disease in expiration, which is carried on so strongly by the diaphragm, the abdominal muscles, and perhaps by serratus magnus, acting from a fixed scapula.

Thus, in epilepsy, the spinal manifestations of functional derangement of medulla oblongata appear to find an explanation. In the same way the cerebral disturbance may be accounted for. Drs. Kussmaul and Tenner are of opinion "that both the loss of consciousness and the convulsions of epilepsy, are the result of sudden and extreme anæmia of the brain."[2] I cannot reconcile that conclusion with more widely known facts. The most fearful bleeding, as from wounds of large arteries, or from rupture of aneurisms, or of the heart by a shell in war; the appalling flooding occasionally met with in the puerperal state, the profuse and rapid hæmoptysis which sometimes ushers in pulmonary phthisis, are not necessarily attended with convulsions and insensibility. On the contrary, such cases are more frequently marked by mental acuteness, and physical relaxation, or composure. The latter condition is often affectingly apparent after death from gun-shot wounds of the heart, or from bursting of aortic aneurisms. Kussmaul and Tenner have endeavoured to prove their theory by tying the arteries which supply the brain in animals, whereby epileptic symptoms were produced. Are we, therefore, to refer those conditions solely to anæmia! Certainly not. They may, and often do, arise from hyperæmia, as in some forms of apoplexy and laceration of the brain. Ligature of the arteries to that organ arrests its circulation, but how such results in anæmia and epilepsy is not evident. Such conditions, could we conceive them to exist, would be in violation of a great principle of the "circulation"—the avoidance of a *vacuum* in the heart and great vessels—so admirably provided against by contractility and elasticity, molecular attraction, and *vis a tergo.* This anæmic theory is also opposed to a generally accepted opinion, endorsed by Brown-Séquard, that, in a fit the pulmonary functions are interrupted, the right side of the heart engorged, and the venous blood reflected upon the brain. It is unnecessary to pursue those theories any further. The sum of the labours of many great minds engaged upon this subject, has afforded a simple and rational explanation of epileptic phenomena, and has been announced by the persevering Van der Kölk, who fixes the starting point of the malady in the medulla oblongata—an impulse from which is communicated on the one side to the muscles of the extremities, causing convulsions, and on the other to the cerebral lobes, inducing loss of consciousness. In his pathological investigations of epilepsy, Van der Kölk found enlargement of the capillary vessels, and granular degeneration of medulla oblongata; and M. Hall remarks that, "every function of the nervous system is involved in the pathology of epilepsy." Hence, a slight increase of tonic condition of the sympathetic nerves will diminish the vascular supply, and may so suspend consciousness.

Viewed under those aspects, we find a gratifying solution to the many difficulties of the present case. Here the disease assumed a chronic character. It wanted the frequent repetition of fits and insensibility, which usually characterize acute epilepsy. It was, nevertheless, serious, perhaps rare, in its presenting permanent epileptic symptoms which, under certain circumstances, might end in the more lamentable type of the disease. A careful investigation of the case rendered pretty certain the diagnosis, which would have been doubtful had examination of the spinal region been neglected. The history of the case appeared to point to hereditary taint, rather than to cold caught after violent exercise, in youth, as predisposing to the malady. If it originated in the former, according to Dr. Russell Reynolds, and other high authorities, the attacks should assume the more grave form, the *haut mal.* Such was not the case. Whatever may have remotely led to this illness, there can be little doubt that the proximate cause was chronic congestion, or a low inflammatory condition of a portion of the cord, as above indicated. The grounds, *a priori*, which sustained this opinion were—the tenderness and other abnormal conditions of the spine, and the constitutional symptoms referrible to derangement in that region. The result of my alterative, and counter-irritant treatment has, I believe, confirmed the diagnosis.

The pathological view which I had taken of the case, suggested the much-extolled bromide of potassium, for its alterative and hypnotic qualities, as the most suitable remedy. After having given it, in large doses for about a month without benefit, I discontinued it, and resorted to the less fashionable, but more venerable bichloride of mercury, which here and in similar cases proved so satisfactory to me. No doubt there are instances, as from nervous irritability, in which this salt may effect a cure. But to hold, as some do, that it is always a specific in a disease so variable in its causation and pathology is unreasonable. As well may we say, the same medicine will remove every pain, or the same hat fit every head. In my former paper, I mentioned a case of the *petit mal*, then under my observation, which has since completely recovered by the use of quinine and iron, with hygienic and tonic adjuvants. It originated in leucorrhœa and general debility. Dr. Chapman, of London, has relieved some epileptics with the spinal ice-bag. Vascular and nervous excitement of the spine appear to have been the pathological causes in these examples. Brown-Séquard effected cures by various means: in one case, by paring off a small bit of highly sensitive cuticle from the under part of the great toe. Dr. Duncan, of this city, found mercury successful when syphilis originated the disease. Dr. O'Rorke, of Enniscorthy, speaks very highly of *artemesia vulgaris* and mug-wort beer, which he administered with great advantage to the epileptic inmates of the workhouse under his care. In fine, there are some cases which defy all remedies. Such a one is recorded as having ended fatally a short time ago. A post-mortem examination proved it to have originated in irritation of the liver, caused by a pin long previously swallowed, and which had penetrated that organ.

Hospital Report.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief notes by Dr. Tonge.)

Bronchitis.—Caroline C., æt. 27, servant. Admitted January 12; discharged January 27. In hospital 15 days. *Recovery.* Subject to winter-cough. Previously ill 6 weeks. Cough and scanty expectoration. A little sibilus over lungs. Pulse 80; respiration 20. Headache; no appetite; tongue red; sleeps badly.

Carbonate of ammonia, chloric ether and conium (14 days). Then quinine and sulphuric acid.

Bronchitis—Laryngitis.—Mary A. M., æt. 23, servant. Admitted March 29; discharged April 16. In hospital 18 days. *Recovery.* Hoarseness and cough 3 months; stridulous inspiration 3 weeks. On admission, scanty eruption on face; pains in bones, worse at night; skin hot and dry. Headache; bad appetite; tongue coated, red at tip and edges; noisy inspiration; no laryngeal tenderness; slight dysphagia; wheezing all over chest. Pulse 124, respiration 24.

Liq. ammon. acetatis, sp. ammon. arom. and chloric ether; steam inhalation; turpentine stupes; afterwards iodide of potassium.

Bronchitis.—Ann D., æt. 46, cook. Admitted February 5; discharged March 19. In hospital 43 days. *Recovery.* Winter-cough 3 years; worse last month. On admission, expiratory sibilus over lungs; copious frothy muco-purulent expectoration. Pulse 96. Tongue slightly furred.

Chloric ether, ammonia, and ammoniacum (8 days); same with squills and henbane (16 days); then syrup of iodide of iron and cod-liver oil; turpentine stupes.

Chronic Bronchitis.—E. P., æt. 33, King's College Hospital nurse. Admitted October 29, 1863; discharged January 20, 1864. In hospital 83 days. *Much relieved.* Winter-cough 18 years. Previously ill 4 weeks. Rhonchus and sibilus all over chest. White frothy expectoration; 48 days later well and able to work; 11 days later fresh cough and shortness of breath.

Carbonate of ammonia, chloric ether, liq. ammon. acetatis, and senega.

Chronic Bronchitis.—E. P., æt. 33, nurse, King's College Hospital. Re-admitted February 11; discharged June 6. In hospital 115 days. *Recovery.* Previously ill 10 days. On admission face puffy; considerable dyspnœa. Rhonchus and sibilus all over lungs; crepitation at bases. Pulse 116, respiration 32.

Chloric ether, ammonio-citrate of iron, aromatic spts. of ammonia and squills; quinine and sulphate of iron; sp. ammon. arom. and ammoniacum; chloric ether, ammonia, and tinct. lobeliæ; henbane and conium. Brandy. Turpentine stupes.

Emphysema and Bronchitis.—W. D., æt. 58, tripe-dresser. Admitted March 28; discharged May 7. In hospital 40 days. *Relieved.* Short-winded 12 months. Previously ill one month. Severe rigors; cough and expectoration; œdema of legs three weeks. On admission cough troublesome; urine one-half albumen, turbid with lithates; pulse 68, respiration 28; physical signs of moderate emphysema; slight crepitation and rhonchus at bases of lungs; appetite bad; urine free from albumen a few days before discharge.

Chloric and sulphuric ether (13 days); carbonate of ammonia (four days); dilute muriatic acid, chloric ether, squills, and bark; purgatives.

Emphysema and Bronchitis.—D. D., æt. 59, waiter. Admitted May 23. *Died* on May 25. Subject to winter cough; worse last few days. On admission, face dusky, nails and lips blue; great dyspnœa; much wheezing over front of chest; pulse 108, locomotive, respiration 44; urine albuminous; no dropsy.

Carbonate of ammonia, chloric ether, and decoction of senega; aperients; dry cupping to back.

Emphysema and Bronchitis.—Maria S., aged 38, married. Admitted Nov. 9, 1863. *Died* on Jan. 18, 1864. In hospital 70 days. Was discharged relieved about a month ago. Increased œdema of legs and dyspnœa 14 days. On admission, face livid; legs œdematous; slight ascites; much cough and shortness of breath; frothy expectoration; pulse 104, respiration 36; sibilus all over chest; crepitation at lower part in front and left posterior base; dulness at right posterior base; trace of albumen in urine; the dropsy increased; dyspnœa became severe about fiftieth day; six days later the right external jugular vein became hard, swelled, and painful; two days later right subclavian vein swelled and painful; face and right arm œdematous; four days later skin sloughing in places; gradually sank and died on January 18.

Post-mortem.—Right lung universally left partially adherent; lungs gorged; o.i. fluid in pericardium; right auricle and ventricle full of blood and much dilated; tricuspid orifice dilated; firm clot in right innominate subclavian, axillary, and internal and external jugular veins; much fluid in peritoneum; livér slightly cirrhosed; kidneys congested.

Carbonate of ammonia, chloric ether and senega (50 days); then ammonia and ether; brandy 12oz.; purgatives, sedatives, mustard emetics, turpentine stupes, pepsine.

Emphysema and Bronchitis.—J. K., æt. 37, hatter. Admitted January 2. *Died* January 4. In hospital 2 days. Formerly in King's College Hospital for bronchitis. On admission much ascites and anasarca. Face blue; severe cough and dyspnœa. Became comatose.

Post-mortem.—Fluid in pleuræ, pericardium, and peritoneum. Lungs gorged and emphysematous. Heart 19 oz. Right ventricle as thick as the left. Tricuspid and aortic valves thickened.

Carbonate of ammonia, chloric ether, squills, and senega. Brandy 6 oz. Jalap and bitartrate of potass. Turpentine stupes.

Pleurisy.—Maria L., æt. 9. Admitted February 17; discharged February 27. In hospital 10 days. *Recovery.* Has angular curvature of spine at 11th dorsal vertebra; anæmic. Previously ill 1 week. Pain in upper part of abdomen, and general feeling of illness. On admission dulness and feeble bruit at right base. Tongue slightly furred. Pulse 80.

Cod-liver oil and syrup of iodide of iron.

Pleurisy.—Mary A. R., æt. 24. Admitted June 7; discharged June 25. In hospital 18 days. *Recovery.* Acute rheumatism 3 years ago. Previously ill 2 days. Acute pain and tenderness at right scapular angle; pain in knees; vomiting; cough; and expectoration. On admission tongue furred. Pulse 106. Rhonchus over lungs; slight dulness at right posterior base; 2 days later pleuritic rub at right scapular angle; 3 days later free from pain, no rub. Pulse 80.

Chloric ether and liq. ammon. acetatis (7 days); quinine and iron.

Pleurisy.—Harriet T., æt. 27, draper's assistant. Admitted February 26; discharged April 2. In hospital 36 days. *Recovery.* Previously ill 14 days. Pain in right side; paroxysms of dyspnœa; occasional vomiting; expectoration sometimes streaked with blood. On admission pallid; frequent cough; greenish expectoration. Pulse 108, respiration 36. Dulness, feeble bruit, and faint crepitation below angle of right scapula; 3 days later no vesicular bruit below right scapula; pleuritic rub at right anterior base; 10 days later no crepitation or rub.

Liq. ammon. acetatis and chloric ether. Afterwards quinine and iron. Cod-liver oil.

Pleurisy.—Benjamin B., beggar. Admitted June 27; discharged July 20; In hospital 23 days. *Recovery.* Four attacks of pleurisy (right side) in last five years, the last 18 months ago. Previously ill 6 weeks; shivering; pain in right hypochondrium; dyspepsia; thirst; loss of appetite; dry cough. On admission weak and drowsy; sordes on lips and teeth; tongue dry and brown. Pulse 108; respiration 36; dim-expansion of right side; dulness and absent vocal vibration over lower part of right lung; breathing absent at base; distant above; crepitation over upper part of posterior lobe; line of dulness extending to 1 inch above angle of scapula, and 1 inch below nipple; chest free from abnormal sounds on July 16th.

Carbonate of ammonia and chloric ether (8 days). Then quinine and dilute hydrochloric acid.

Pleurisy.—A. A. T., æt. 21, porter. Admitted February 13; discharged March 19. In hospital 35 days. *Recovery.* Previously ill 3 weeks; shivering; headache; vomiting; dyspnœa; pain in right side. On 3rd day after admission slight dry cough; pulse 92; respiration 32; dulness and absence of breathing and vocal vibration below 3rd rib in front, and 1 inch above scapular angle behind; tongue dry and red; appetite bad; bowels confined; urine one-half albumen (free from albumen 3 days later). 23 days later, dulness over whole of right lung; friction sound below right nipple.

Liquor ammon. acetatis, sp. ammon. arom., and tinct. camph. co. (12 days). Then dilute muriatic acid, quinine and chloric ether. ol. morrhuæ. E. L. to right side.

Pneumonia.—E. N., æt. 62, carpenter. Admitted January 29; discharged February 20. In hospital 22 days. *Recovery.* Three weeks ago, after rigors, was laid up for a few days. Four days ago, vertigo, nausea, dyspnœa, cough, and rusty sputa. On admission, cheeks flushed; skin hot and dry; headache; shortness of breath; pain in upper part of abdomen. Pulse 104; respiration 32. Dulness and medium crepitation over right lung, below 4th rib in front, and scapular angle behind; bronchial breathing and bronchophony behind, pleuritic rub in front; 3 days later crepitation up to scapular spine behind, and 2nd rib in front; 9 days later crepitation to 1 inch below scapular angle; 7 days later breathing clear; appetite good.

Liquor ammon. acetatis, chloric ether, sp. ammon. arom. and tinct. scillæ. Afterwards quinine and dilute muriatic acid. Brandy 12 oz. Turpentine stupes.

Pneumonia.—H. H., æt. 17, groom. Admitted December 1; discharged December 31. In hospital 30 days. *Recovery.* Subject to cough. Previously ill 3 days. Pain in limbs and left side of chest; cough; expectoration; loss of appetite, and feverishness. On admission, skin hot; headache; tongue coated. Pulse 116. Dulness; diminished vocal resonance, and thrill; fine crepitation, and some bronchial breathing below left scapular; blood streaks in expectoration. Much epistasis after admission. Lung normal on 15th day.

Liq. ammon. acetatis (7 days); aromatic spts. of ammonia, chloric ether, and liq. cinchonæ (9 days); then quinine and dilute hydrochloric acid. Blisters. Aperients.

Pneumonia.—Henry M., æt. 17, no occupation. Admitted March 28; discharged May 28. In hospital 61 days. *Recovery.* Has lived badly of late. Previously ill 1 week. Shivering and lassitude; deafness and drowsiness. On admission, face flushed; skin hot and dry. Pulse 120; respiration 40. Expectoration more or less rusty till 37th day after admission; deeply tinged with blood on 17th day after admission. Dulness; fine crepitation, and increased vocal resonance over right base; 10 days later bronchial breathing and crepitation below scapula; 19 days later lower two-thirds of right lung dull; bronchial breathing and fine crepitation at scapula angle; dulness and harsh breathing at left base; 17 days later breathing everywhere vesicular.

Liquor ammon. acetatis, arom. spts. of ammonia and squills; afterwards dilute muriatic acid, squills, chloric ether, and liq. cinchonæ; cod-liver oil. Aperients. Brandy 12 oz.

Literature.

THE RECONSTRUCTION OF THE ARMY.

That the entire system under which our army is at present recruited, officered, and administered will at an early date be subjected to a more severe criticism than it has yet undergone, is now evident. Mr. Trevelyan has already prepared the House of Commons for what promises to be a successful onslaught against the disposal of commissions by purchase. The Treasury and a large portion of the press have condemned the double government under which this branch of the public service is administered; and now Sir Charles Trevelyan[1] has published an excellent treatise, in which he clearly points out the existing defects and their remedies, having in view nothing short of the reconstruction of the entire military machine.

In no other state of society than the army of this country do the old usages of feudalism still remain in force. Between the officer and the private a great gulf exists. The distinction is essentially one of caste; but like many other usages of mediæval times, it must give way with the advance of opinion. That the army should be anything else than a representation of the nation; that it should be either more aristocratic or more democratic than the rest of English society, seems monstrous; and that perseverance and proved worth should not obtain the same position of fortune and distinction in the military service that they command in other positions in life, is a principle far behind the spirit of the present time. The question comes to be, how are these conditions to be improved? The answer immediately follows, abolish purchase, and increase the pay of all ranks sufficiently to enable them to live upon it in a suitable manner; or, in other words, make the infantry and cavalry branches of the service what the artillery, Royal engineers, and several departmental corps are, a life long profession for the officers who join them. Another innovation, in regard to present usages, would be the promotion of an increased proportion of non-commissioned officers to commissions, a measure which, probably more than anything else, would serve to induce the yeomen class of our countrymen to enter the army, and thus indirectly undermine much of that spirit of *restlessness*, to call it by no harsher name, which, it is to be feared, is sown somewhat freely among the partially educated of our population.

As to the question of retirement, there need be no greater difficulty than now exists in regard to the corps and departments in which promotion by purchase is not now observed; and it may be assumed that as with them the applications are few to retire, or for leave of absence, in times of active service, the country would considerably gain by the substitution of such a state for that which was attributed to purchase officers during the Crimean war and the Indian mutiny.

That the volunteers and militia are, in their present condition, utterly useless as a means of defence seems to be all but universally acknowledged, and that our regular army is hampered and burthened instead of strengthened, by the numbers of old soldiers in its ranks, is a fact which has, perhaps, become more apparent than it was before, since General Trochix called attention to a similar defect in the French army. Sir Charles Trevelyan would remove both evils by instituting an army of reserve, upon a footing which he details, and which is in many respects different from the principles in which the force under that name is now being instituted. He would reduce the term of first enlistment from twelve to seven years, thus young men would generally leave the service at twenty-five, most of whom, he thinks, would join the reserve and settle down as married men. It is to be feared, however, that only in the United Kingdom, if even there, would his hopes be at all realised. Abroad, and especially in India, the greatest rate of mortality prevails among men under twenty-five years of age, and those who survive that period would, in all probability, not be generally disposed to return to Britain. Another of his suggestions is a most excellent one. He would have regiments quartered in the counties to which at present they but nominally belong; he would have the regiment of militia somewhat in the nature of a second battalion to that of the line, instead of the present anomalous depot battalion system, he would have regimental depots as of old; and we may add that, according to our view, were the corps of militia to be officered by line officers in the reserve list, as the soldiers of that description, the bond of union between the various branches of our military forces would be much more intimate and stronger than it now is.

---

[1] "The British Army in 1868." London: Longmans, Green, and Co.

On the subjects of marriage in the army, and on the vice of drunkenness among the soldiers, we cannot now enter. Suffice it to observe that the pamphlet on which our present remarks are based is an able and suggestive one, and well deserving the serious attention of all who are interested in the question of the military force of our country.

CHOLERA AND WATER.

It will naturally be expected that a journal which has devoted so large an amount of space to the theories of cholera, should notice the last manifesto in favour of the water theory. Dr. FARR of the Registrar-General's office, has summed up in his report, which, with the appendix, extends to 400 pages, the account of the epidemic of 1866, and his conclusions from the facts recorded. We may state at the outset that Dr. FARR remains of the same opinion as he has hitherto expressed as to the outbreak having been due to the distribution of unfiltered water by the East London Company.

It is not our object here to controvert his conclusion; indeed, we have no wish to take either side in the controversy. We have given full space to the several theories; we have discussed the objections to Dr. FARR's hypothesis, because too many of our contemporaries had closed their columns to all that did not agree with it, but we have no intention of imitating their tactics, by refusing to give currency to Dr. FARR's opinions, which are entitled to the greatest respect, and which, we are sure, that able officer would himself wish to see subjected to criticism.

We shall, therefore, give to some extent, in his own words, a brief outline of the report in question. It starts with the statement that in the East London water-field nearly 4000 persons were carried off, while in other districts the epidemic was not more severe than might be anticipated from the diffusion of cholera-matter through sewers and other modes of distribution.

Dr. FARR speaks of the objections that have been urged to his views under the head of statistical fallacies, but no doubt his opponents will be ready to argue that his own conclusions would be correctly described in those terms. He says:—

> "One fallacy necessarily makes a strong impression upon the mind. House after house supplied with East London water can be taken in which no death, or even case of cholera, occurred; and here the reasoning takes this form:—These houses were supplied with the East London water during the epidemic; they were not visited by cholera; therefore the East London water was not the cause of cholera. This fallacy turns on the use of the word 'water' in two totally different senses. No one for a moment pretends that pure 'water' can be the cause of cholera. It is some matter in that 'water,' the word serving to designate in chymistry a compound of oxygen and hydrogen, but in common usage a fluid consisting of the most various compounds, inorganic and organic, in the state of germ, of full life, or of death; and compounds, too, which must necessarily, from the nature of the water supply, be unequally distributed in the waters—in one house in inconceivably small quantities, in other houses in large doses, in one house among susceptible, and in other houses among insusceptible people. To show that a portion of this water is taken with impunity, and still less to show that the people in certain houses in East London did not die of cholera, is no proof whatever that the cholera leaven was not present and fatal in other portions of the East London water supplied to other houses. Eels, as we have seen, were found in the water of a certain number of houses in East London. To argue that in hundreds of other houses no eels were found, and that, therefore, the company never distributed eels in the district, would be absurd. The fallacy of such reasoning is transparent. It assumes the form—if no eels are found in the waters of a certain number of houses, none exist in the waters of any houses. As the eels are limited in number they cannot be distributed universally, and the fact that they were discovered in one house and not another would depend on laws and circumstances so intricate as to make the ascertained distribution anomalous, but not necessarily more anomalous than the distribution of the lower forms of organised matter to which the phenomena of cholera in man are due."

Now here it will be observed many conjectures are taken as if they were well-ascertained facts. We do not think objectors can be fairly charged with using the word water in the loose way stated. We have read more that has appeared on the subject, and that fault has not appeared to us so palpable. Again, the comparison with eels is altogether beside the mark. Granting that there may be a ponderable, physical, poison as the cause of cholera—and this is granting more than can be proved—is it fair to compare eels, of dimensions large enough to stop up the pipes, with the minute, invisible particles conjectured to exist, and which Dr. FARR himself calls "leaven," and in other ways describes as necessarily polluting the whole mass of water to which they have gained access? It seems to us, as impartial spectators of the controversy, that this argument is of no value. It might as well be asserted that because particles of sand or dirt are found in our cisterns, therefore cholera-poison is also there Indeed, this would be more pertinent, for small particles like this find access to every cistern in London, simply, we fancy, because they are small, and are thus easily carried along in the stream. Why, then, should not the infinitely smaller and lighter cholera-germs be as equally distributed?

This question will be seen to be of greater force if we look to the explanation offered us of the immunity of North Woolwich and Stamford Hill, though drinking the same water. Dr. FARR writes as follows:—

> "As the direct distance from the Old Ford reservoir to North Woolwich is above four miles, and the water appears to travel along one low arterial main, which is kept always full, it is evident that if suspended cholera matter undergoes any change it will be modified before it reaches North Woolwich, and will necessarily be diluted as the heavier molecules fall down on the way. The main leading up to Stamford Hill (about three miles and a-half) will by gravitation be prevented from conveying all the matter of a heavier specific gravity than water up to the height of that reservoir. But such a sudden influx of the pond water of Old Ford as is described by the witnesses would be injected at once with some velocity into the near empty pipes, yielding water on the intermittent system. And here one of the many advantages of the constant system of supply is evident: under it fresh zymotic matter is less likely to be thrown into people's dwellings at a distance.
>
> "In the two remoter regions the epidemic took the milder form of diarrhœa, and this may be due either to the accidental diversion of the matter from their mains, or from its greater dilution and age."

Now, we think it would be quite fair to reply that the cisterns at Woolwich and Stamford Hill contain plenty of mud—particles of matter that have been brought by the water, and have settled down after it is at rest; particles, too, thousands of times heavier than the germs supposed to be distributed so irregularly, and some of which are thus suggested to have settled on their way by mere force of gravity.

If it be also assumed that these germs rapidly propagate at ordinary temperatures, out of the body, the argument of dilution loses much of its force, but this assumption seems almost too much to ask, and therefore Dr. FARR sets himself to account for the facts on the less daring hypothesis:—

> "It may appear at first sight impossible that the cholera flux of one or more patients should produce any effects in the waters of a river like the Thames. The average quantity of this flux is large, but it has not been determined directly, and it varies with the severity or the duration of the disease. Applying Pacini's data to the fatal cases of different durations, it is found that the average volume of the dejections in a cholera case is equivalent to 8·24 litres. How many cholera corpuscles this quantity contains cannot be calculated. They are exceedingly minute. By Pacini's estimate 1000 millions would not occupy more space than a cubic millimetre; and there are a million cubic millimetres in a litre of water. The number of litres in the river Lea at high water is 1416 millions; at low water, 142 million litres. And, according to Vierordt, one litre of blood contains about 5069 million globules, consequently, the corpuscles in the eight litres of the flux from a patient, if in equal density, would run up to 41,566 millions. It is certain that the flux finding its way down the sewers would not be equally distributed in the river Lea for instance, but in the water would be in irregular masses like clouds in the sky; and that at some points a quart of the waters might contain hundreds or thousands of corpuscles capable of propagating their numbers by millions in the mucous membranes of the stomach and intestines. Whether the cholera corpuscle can propagate itself in sewage water at a high temperature is not yet known, but its diffusion is adequately accounted for on the hypothesis that it is only propagated in the living organism."

Nothing could show better than this quotation the infinitely small particles with which the hypothesis deals, and consequently the force of the contrast we have ventured to make between them and the grosser, visible, palpable particles of matter that are distributed so equally in all our cisterns.

In running rapidly through this important report, we have thus, as will be seen, noted a few things to which we venture to take exception. There are other points to us equally doubtful or hypothetical, but we need not dwell further upon them, as we have no doubt that able men will at once examine and sift the facts and conclusions. It is from the conflict of views that may occur that we may hope for some further enlightenment.

The report contains a vast mine of facts and statistics, and will, no doubt, be the armoury whence both sides will draw their weapons. The statistics, as a whole, of the several water-fields, for instance, present figures that will, in the opinion of many, amply justify all that has been said by Dr. FARR; and after what we have written, it is but fair to state the summary. We find, then, that the mortality from cholera in 1866 in each of the water-fields of London thus given:—The proportion of deaths to 10,000 inhabitants was four in the field of the Chelsea Company, four in that of the West Middlesex, three in that of the Grand Junction (the proportions being nearly the same where the districts were supplied conjointly by these companies), four in that of the West Middlesex and New River, eight in that of the New River, thirty-four in that supplied conjointly by the East London and New River, seven in that of the Southwark, fifteen in that of the Kent, three in that of the Lambeth, six in that of the Lambeth and Southwark conjointly, six in that of the Lambeth, Southwark, and Kent conjointly, and seventy-three per 10,000 inhabitants in that of the East London Company.

Figures like these certainly deserve serious attention, and whether the assailants of what we may now, we suppose, call the official theory of cholera, succeed in disproving it or not, it is well that they should be published as widely as possible. Indeed, all statistics of this description have a high value, and we regret that want of space prevents us from entering at present upon many other subjects which are opened by the report before us.

We can only here add that much information is to be found in this volume, not only about the epidemic in London, but throughout the country; while in connection with the former part, the various plans for supplying the Metropolis with water are discussed, and the propriety of seeking our supply from a distance is urged, although full justice is done to the attempts of the several companies to comply with the Water Act.

◆

Notes on Current Topics.

Oxford University.

THE gates of the University of Oxford are to be no more closed to all who cannot afford to enter her aristocratic Colleges, or will not submit to their rules. The youth of the country are freely invited to enter the Mediæval University, select their own tutors and their own lodgings, live in the manner they have been accustomed to do, or may wish to try and avoid or choose associates as they please.

"Unattached" undergraduates will be free to select any of the "licensed tutors," who will, as it were, be the "heads" of colleges or communities having no fixed residence.

We cannot doubt that there are many who will see in this a great stride, and will rejoice to see an Oxford career thus freely opened to all; and we hope the University may attract its share of the young men who may adopt the Medical Profession.

We can well afford to increase the small proportion of Oxonians in our ranks. A single year at Oxford before beginning professional study must prove of great value, but we hope many will go and take a degree in arts as their preliminary examination.

London Hospital.

At a recent Court of the Governors, it has been resolved that in future the style of Physician or Surgeon shall be conferred on those members of the assistant staff who have held office for seven years.

Under this regulation, Dr. Langdon Down and Mr. Maunder will henceforth have respectively the title of Physician and Surgeon to the Hospital.

An additional Assistant-Physician and Surgeon is about to be appointed.

The "Dreadnought" Hospital Ship.

We regret to learn that the Committee of the Seamen's Hospital Society, despairing of obtaining funds to build on the site which they purchased some time since, or obtaining from the Government any suitable accommodation in Greenwich Hospital, are putting the old "Dreadnought" into repair for an expected continuance of its occupation. The patients have been temporarily transferred to the "Belleisle," and, we believe, only wait the repairs of their former quarters to be sent back to it. It is a standing public disgrace that the sick of the merchant service should have no more suitable refuge than an old hulk, cramped and inconvenient as a ship must necessarily be, and enveloped from year's-end to year's-end in a fog of Thames miasmata.

The West Middlesex Coronership.

The legal question in connection with the late election of Dr. Diplock as coroner has again been before the Middlesex magistrates. As yet, Dr. Diplock, though he discharges the duties of the office, has not obtained a shilling of salary, and the magistrates have again declined *pendente lite* to take the responsibility of paying over the money. On this occasion, Dr. Diplock offered the magistrates an indemnity for the amount, but his request was refused again, and we learn that after all, if the election should be declared invalid, the sitting coroner will not get a shilling for his services, but the salary will go to Dr. Hardwicke. It is a valuable privilege of suitors at law, that they are permitted to work hard, while their attorneys are spinning the endless thread, and that they have the agreeable incentive of knowing that very possibly the fruit of their labours will go to their antagonist.

The British Association for the Advancement of Science.

The great Norwich meeting, referred to in our last, has taken place, and will unquestionably rank as one of the most successful.

Norwich has, indeed, this year been highly favoured, for in addition to this great gathering of scientific men, it has been able to show what its own Fine Art Association can do.

It has further inaugurated a Norfolk and Norwich Horticultural Society; and the third session of the International Congress of Prehistoric Archæology is now sitting in the quaint old city.

The routine business having been transacted during the day, in the evening the Duke of Buccleuch, in a brief speech, yielded the office of President for the year to Dr. Hooker, who then delivered his inaugural address. This was an able review of the past year's progress in science, especially in fossil botany and vegetable physiology, and a masterly criticism of the Darwinian philosophy.

The Annual Report of the Scottish Registrar-General.

This report has been completed for the year 1865, and the curious will there find abundant information on the births, marriages, and deaths.

To the last item we turn first, as that most thoroughly within our province, though the two others are almost of equal concern to us.

In Scotland, the death-rate for 1865 was one-and-a-half per cent above the average of nine years. The country districts showed a much lower proportionate mortality than the towns. In the death-rate of the eight principal towns, the variation is very great. Leith is at the bottom of the scale, with 24·9 in the 1000, and Greenock is at the top, with 39·5 per 1000. When we come to the statistics affecting the infants under one year of age, Greenock still shows the same high-rate, full of foul smells, bad living, overcrowding. In Greenock, out of every 1000 children born in 1865, it is recorded that more than 25 per cent. perished in the first year of their age. Figures like these demand the attention of the local authorities.

The Penalty of Unqualified Practice.

The Medical Practitioners of Oldbury, who have taken so decisive a position in respect to the scale of sick-club remuneration, have succeeded in striking a further severe blow against the underselling system. They prosecuted a person named Holland for having, without qualification under the Medical Act, issued a death certificate, in which he described himself as Surgeon; and secondly, for having acted as Surgeon to a Friendly Society. Despite every effort of the prisoner's counsel to raise a technical defence, both charges were declared proved, and a fine of £5 imposed in each case. There were nine other accusations, but they were all withdrawn, the object of the prosecution having been attained.

The Chair of Botany in Trinity College, Dublin.

The election to this chair, to which we recently alluded, is necessarily postponed to a distant period by the regulation which requires that it shall not take place for at least three months from the advertisement of the vacancy. To the names of Dr. Edward Percival Wright, Dr. Browne, and Mr. McNab, which we have already mentioned, those of Mr. Cleghorn and Mr. William Archer, the well-known physiological botanist of Dublin, have been mentioned. We are in a position, however, to state that the latter gentleman has no present intention of seeking the vacant professionate. As the interval before the election is so distant, and the position is now open to the competition of "all persons," without religious, professional, or academic reservation, it is not improbable that other candidates may yet present themselves.

The Naval Medical Service.

Be the causes of the dearth of Naval Surgeons what they may, there can be no doubt that the Admiralty is at this moment in a state of blockade, and the garrison is all but starved out. Their beleaguered Lordships are hard pinched for medical nutriment, and they are—if the *simile* be not considered disrespectful—almost brought to the alternative of what is known as *boot-eating*. The choicer morsels of the Profession have long since been strange in Somerset House, and the medico-educational dietary of their Lordships comes to be selected on the simple principle of taking what they can get, and thanking Providence it is not worse.

If we are to accept the report of the Naval Medical Competitive (save the mark !) which we have received from a reliable source, we should denounce the examination as a farce played out to satisfy the public with the poorness of the actual performance. We narrate our story from the lips of a successful candidate who has accepted service, and is an entirely unprejudiced witness.

On a stated morning the candidate presents himself at Somerset House, and submits his certificates to examination by a clerk, who, we will suppose, is satisfied with them, and orders the candidate to be brought up for the ordeal the next morning at a specified hour. In a state of semi-collapse, inadequately neutralised by a diffusable stimulant, the trembling candidate punctually appears. He waits an hour (stimulant effect passed and gone, and the reaction of depression developed), when he is handed a single written question of the simplest kind, to which with pleasurable alacrity he writes an answer at the clerk's desk on the back of a ledger, and is charmed to learn that he may depart, which he does with remarkable nimbleness —and thus his second day of examination. On the morning of the third day he is put through a physical investigation, and stowed away in a musty waiting-room for half-an-hour. He is then summoned to the presence of the dread Triumvirate, who proceed to examine on muscular anatomy, and wind up with *two* questions in surgery. Having answered or missed these questions, the candidate is again remitted to solitary confinement for a short time, during which period, it is presumed that he is declared learned in the whole art and mystery of anatomy and surgery. The same process then followed with questions in physiology, practice of medicine, and midwifery, and the prisoner again remanded to a new examination in botany, materia medica, and chemistry. An awe interval for the consideration of sentence, and the happy chosen is an Assistant-Surgeon in her Majesty's hospitals and fleets. The entire process, with intermediate delays, occupied less than two hours, and, be it said with horror, left the impression on the irreverential mind of the candidate that the whole affair was a farce, and that two out of the three examiners accepted his answers *sub silentio*, being a little doubtful in their own minds whether the reply was right or wrong. No record of the answering was kept, as far as the candidate could observe, and the question is cogently asked, on what principle does the Admiralty carry out its guarantee to promote the best answerers to their surgeoncies at an earlier period than would occur under ordinary circumstances.

The examinations for the admission of Assistant-Surgeons into the Army were concluded last week, and in our last issue we gave the printed papers, which have been read with interest. For the first time the test for the selection of candidates has been really competitive, for the Director-General has been in the position of rejecting eligible candidates, the entire number of vacancies having been filled up. At the Chelsea examination 39 candidates presented themselves for 21 vacancies, of these a greater number than the 21 evinced sufficient proficiency for the service, but were sent back for want of room.

It would appear not only a hardship on these gentlemen to compel them to go through a second examination, having once tested their competency, but injudicious on the part of the authorities to refuse suitable candidates at a time when they experience so great a difficulty in meeting the requirements of the service.

We are favoured by Mr. Richard Griffith, resident at Mr. Barter's Hydropathic Establishment at Blarney, with a printed copy of his "reasons for objecting to the process of vaccination," published by him as a protest against a prosecution instituted by the Cork Guardians for omitting to have his child vaccinated. With every desire to do Mr. Griffith justice, we cannot transfer to our columns arguments and statements against which not only the entire profession, but (with an utterly insignificant exception) the whole educated community have made up their minds. We cannot, however, but notice the fact that the entire basis of the anti-vaccination argument is ridiculously illogical, when regarded from practical grounds. It is persistently declared by the opponents of vaccination that it ought to be discountenanced, because it implies the deliberate introduction into the system of a poisonous virus. We need not proceed to argue the totally unproven statement that the vaccine virus is neither, in its effects on the system, or in any real sense of the word, a poison. It appears sufficiently ridiculous for any person to declare that it is "sinful" to substitute a comparatively harmless antidote for the risk of a loathsome and dangerous disease We presume that no one would vaccinate if there were nothing to be avoided by the process, yet is pure nonsense to fulminate against the adoption of a safeguard, even if we are to call it a poison, for an enormously disproportionate risk. If the anti-vaccinators have no better reason than such special pleading, and no better scientific testimony to adduce than that of Dr. Collins and Dr. Marsden, their cause is unworthy even of discussion. In our opinion it is perfectly right and proper that no individual who may foster a delusion which he has had every opportunity to neutralise, should be permitted to extend the ill results of his monomania to the detriment of the health, or the endangerment of the lives of those whom he may be in a position to control.

The Cattle Plague Orders.—A splendid heifer, a present to her Most Gracious Majesty the Queen of Great Britain, from his Serene Highness the Duke of Saxe Coburg, arrived in Hull by steamer on the 14th inst. The orders of the Privy Council as to cattle, direct that all foreign cattle landed at Hull shall, after a specified time, be slaughtered. The heifer from Saxe Coburg, although consigned to the Queen, was therefore detained, and is still in Hull in the keeping of the Custom-house authorities. Fortunately for the life of the heifer one order of Council has a clause allowing the cattle to go seaward, so on Saturday next her Majesty's present will, under a bond for £100, be forwarded by steamer for London, and there she will be transhipped to Southampton, from whence, after a quarantine of 28 days she will, under a certificate, be taken to the Royal farm at Windsor. This case affords an illustration of the practical difficulties of administering the cattle-plague orders of the Privy Council.

REPORT ON WINE AND ITS ADULTERATION.

[SPECIALLY PREPARED FOR THE MEDICAL PRESS AND CIRCULAR.]

No. IX.

WHEN treating last year of port, it will be remembered that we drew special attention to the prevalent custom of over-fortifying, and our observations called forth such confident denials and out-spoken resentment, that we felt constrained to give copious quotations from official reports in confirmation of the conclusions at which we had arrived. These conclusions are, we may fairly boast, now undeniable, and we are confident that what we have to say now upon sherry will be hereafter recognised as equally authoritative.

Yet, as there are plenty of captious persons abroad who know not to what our experiments tend, and are more deferential to authority of a different kind, we shall precede our own statements by those of an official sent to investigate the wines of Spain and Portugal, and to whom we have before had occasion to refer. We allude to Mr. Charles Bernard, assistant - surgeon at H.M. Customs, whose accuracy has never been impugned, and from whom we extract the following paragraphs, which contain a just estimate of the matter up to the time of our taking up the inquiry:—

"The large shippers and vineyard proprietors of Spain and Portugal are, and have been for a long period of time, manufacturers rather than simple producers of wine. The practice said to be followed in other countries, of merely watching and aiding nature in the development of fermentation, has here superadded to it a system of mixing and fortifying that tends to produce an intoxicating rather than a purely exhilarating beverage.

. . . .

"An opinion seems generally prevalent among the growers and shippers that natural wines will not maintain themselves sound unless assisted by the addition of distilled spirit. Even to some extent, where it is not the practice to add spirit to the 'must,' as in the case of the Montilla, Val-de-penas, &c., it is usual, and considered necessary, before the wines are made up for exportation, to add spirit to a greater or less amount. I am not prepared to endorse this statement fully.

. . . .

"It may be as well to give here a resumé of the general practice in the Xeres districts of preparing wine.

. . . .

"No spirit is added to the 'must' during the process of manufacture or pressing the grape at the vineyard, unless it is intended to be made 'sweet wine,' and then six arobas (equal to about twenty-one gallons of spirit, about 60 per cent. over proof) are added, in order to prevent fermentation, and to retain its sweetness; and when this sweet wine is drawn off the lees, about six months after it is made, three or four gallons more spirit are added, making in all between twenty-four and twenty-five gallons spirit to the butt. This sweet wine is not usually exported, but is used for the preparation of other wines intended for the English market, and is added to other wines to give body, flavour, and strength, in such proportion as is deemed necessary according to the style and taste required.

. . . .

"The wines intended for white dry wines, and eventually to be made up into what is known in England as 'sherry,' have about two gallons of spirit added to the butt when drawn off the lees in the month of March or April following the vintage, and during the rearing of them further small quantities, from time to time, as required. Those wines selected for vino fino, Amontillado, and Manzanilla, in lieu of having spirit added to them, are thrown on to Soleras; or fine old mother wines which, by age, care, and attention, have acquired a body and character, and which are used in mixing with other wines, to improve them. The stocks of Soleras are always kept up in the following manner:—

Say 20 butts, 1841; half drawn off for use.
20 butts, 1842; half thrown into 1841.
20 butts, 1843; half thrown into 1842.

And so on from year to year, the younger wine being thrown on to the wine of the year previous.

. . . .

"Notwithstanding the quantity of spirit (two gallons) used in rearing wine (not Amontillado, vino fino, and Manzanilla), it is usual, when it is made up into sherry for England, to add at the time of using it, from two to four gallons more spirit, according to the quality and age of the wine. There is, however, no standard sherry made up, and no regulated quantity of spirit used, as that depends both on the character desired by the purchaser, and (a most important consideration) on what the wine itself requires.

. . . .

"A butt of sherry for England is made up in 40 jars in various proportions; thus, for example:—

1 Jar, spirit, about 60 over proof.
8 Jars, of the sweet wine or dulce.
7 Jars, soleras, or mother wine.
10 Jars, dry wine, 1854.
14 Jars, dry wine, 1859.
——
40

. . . .

"The Amontillado is entirely a chance wine, that is, it cannot be made as a matter of course, or reckoned upon with any certainty, insomuch as out of 50 butts of wine made at the same vineyard, under the same circumstances and with the same kind of grapes, probably only two or three will turn out to be wine of this character. No reason, however, can be assigned for its partaking of the peculiar flavour, &c., of Montilla wine, from which it derives its name.

. . . .

"When the wines are classified in the spring, those which from their taste and style are likely to turn out Amontillado and vino fino are marked in a certain manner, put aside, and are carefully watched and reared, but it does not unfrequently happen that, after the selection, they fall off, and become sick and out of order, when they are treated in the same way as other ordinary white wines, and spirit is added in the proportion deemed requisite to secure them from spoiling; should the wine, however, not recover under this treatment, and acetic fermentation supervene, it is then sent for distillation into brandy.

. . . .

"The wine of Benicarlo intended for exportation is fortified to the extent of five gallons per pipe, though two and a-half gallons would be considered sufficient to preserve it for home use. Here, again, but little stock is kept on hand, each year's produce being generally sold for exportation, or consumed by the time the new wine is made; and it was impossible to procure samples of natural wine of former vintages."

◆

Correspondence.

REPRESENTATION IN THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do not quite agree with all that has been stated by yourself and your correspondents as regards the representation of the profession in the Medical Council. I must say that I think it a bad thing to try to reform the Universities and Corporations as well as the Medical Council *all at once*.

I go in for the direct representation of the registered practitioner in the Council, as distinct from the Crown nominees and Corporation delegates.

The Corporations are not likely to permit their delegates to be chosen by the great body of their constituents, for that would revolutionize the Corporation as well as give *direct* (*not indirect*) representation in the Council. Let us then agree to fight for a representative *principle* in the Medical Council, not for details. If the Corporations will allow their *alumni* to return their member to the Medical Council, well and good—*direct representation* of those *alumni* takes place, but for my own part, I know that the Corporations and Universities *are dead against* the scheme, except perhaps Cambridge, therefore I would not ask for the reform of the Corporations as well as the Council. I think it only right, if the registered practitioner is represented that the Corporate bodies should be represented also, and that if the body of the profession is well represented, that they will require an opposition to keep them from going too far. This opposition they would get from the Corporation delegates, as at present constituted, therefore I am not favourable to the plan urged by Dr. Prosser James, until after that of the British Medical Association has gained the day. It is a question where to begin. I say, reform the Council first, then agitate for reform of the Corporations. It is now clear that all agree that reform is needed, why then can we not settle the relative merits of the two schemes, and all unite our forces to carry one. Splits in the camp are bad things, for our enemies make use of them to neglect or postpone our claims.

I have no wish to push my views, or do anything but aid in promoting unanimity. If the advocates of both schemes joined their forces, sinking details, or discussing together a common base of action, a grand reform would result.—I am, &c.,

M. P. A.

REFORM OF THE MEDICAL COUNCIL—DIRECT AND INDIRECT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The two plans of reforming the Medical Council have been distinguished by you and others as the *direct* and the *indirect*. The names may in some sense serve the purpose, but are not exact.

If the plan of Dr. Prosser James, which you call *indirect*, should be carried out, what would result? As I understand it, the representative of each body would be elected by the persons who held its diploma. Now, these are all medical practitioners; and as all medical men have some diploma, all would have a vote. Those who had more than one diploma would get more than one vote.

Now, is it not clear that persons thus elected would *directly* represent the Profession?—quite as directly, I feel sure, as M.P.'s represent their constituencies.

It seems a mere question of electoral districts or constituencies. What is the use of cutting up the country into new divisions, and bringing up the ghost of "equal electoral districts," to serve one political party, as Dr. Andrew Wood proposes, and as would be the end of the British Medical Association's plan?

We have good and trustworthy constituencies ready made to our hands. University constituencies have now acknowledged claims. Cambridge—all honour to her for it!—has already done justice, according to the letter of one of the Senate in your last number. Let the other universities and the corporations follow the example.

Such constituencies as these are, in my view, most in accord with the constitution, and deserve to be extended. I therefore regard the scheme of Dr. Prosser James as more *constitutional*, and therefore more conservative, than the revolutionary plan of Dr. A. Wood and the British Medical Association.

Therefore, although he belongs to the Liberal party in general politics—as we so much need *medical* men in Parliament, and as our Council, without some change, is as useless as Convocation, I shall vote for him at the election, and hope many others will do the same.—I am, &c.,

A CONSERVATIVE M.D.EDIN.

PUERPERAL FEVER IN LYING-IN HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In THE MEDICAL PRESS AND CIRCULAR of the 13th March, 1867, you noticed some observations that I had recently published "on the comparative advantages of affording obstetric attendance to poor women in lying-in hospitals, and in their own homes." I have since made further inquiries on the subject, and as all the documents that I have been enabled to examine, seem to leave no doubt that the mortality of parturient women is much greater in Dublin, comparatively with the number of births, than in London, or in other large town populations in Great Britain, I shall state, as briefly as I can, the data on which that conclusion is founded. These data are:—1. The returns of the English and Irish Registrars-General. 2. The published Parliamentary Reports of the Board of Superintendence of Dublin Hospitals. And, 3. The printed Abstract of the Registry of the Rotundo Lying-in Hospital.

The mortality of parturient women is assigned by all the Registrars-General to two causes—metria (puerperal fever), and "the accidents" of childbirth, such as convulsions, hæmorrhage, &c., and, as the first, puerperal fever, prevails more in some years than in others, it is necessary, in order to form fair comparisons, that the returns for each country be for the same years, and also that they be for similar communities or populations. With this view I will compare the births and deaths of parturient women in London and in 21 of the most populous cities and towns in England for the three years ended 1866, with those in the returns of the Irish Registrar-General for the Dublin registration district for the same years. I have not yet seen the English returns for 1867, and, of course, cannot compare them with the Irish returns for that year, which have been published.

1. The London births amounted to about 306,000 in the 3 years ended 1866, and 1617 women, or 1 in 189 births died in childbirth in London in these years; 666 of puerperal fever; 951 of the "accidents" of childbirth. The births in the 21 towns amounted to about 396,000 in the 3 years, and 2192, or one in 180 births, died; 737 of puerperal fever; 1455 of the "accidents." In all these populations, 3809 women are returned as having died in childbirth, which is in the proportion of 1 to 184 births; 1463, or 1 in 500 births died of puerperal fever; 2406, or 1 in 292 births, died of the "accidents." These births, and this mortality, include all that occurred in lying-in or other hospitals in London, and in these 21 towns; but I have seen no account of the number of births, nor of the mortality in these hospitals.

The returns of the Irish Registrar-General show that 24,538 births took place in the Dublin Registration district during these three years, and that 207 women, or 1 in 119, died in childbirth; 134, or 1 in 184, died of puerperal fever; 75, or 1 in 340, died of the accidents of childbirth. This high rate of mortality in the Dublin district caused a loss of 74 lives more than if it had been the same as in the English populations, 1 in 184, in which case only 133 would have died. These 24,538 births include 5546 that took place in the Rotundo, and in the Coombe Lying-in Hospitals, as we learn from the published reports of the Dublin Hospitals Board, by which reports the mortality in these hospitals can be compared with that which took place in the remaining 18,992, or the *home* births, in the Dublin district. 3908 women were confined in the Rotundo in these three years, and 1638 in the Coombe; 82, or 1 in 59 births, died in the Rotundo; 12, or 1 in 136, died in the Coombe; and 113, or 1 in 168, of the home births died.

It will be seen by these returns that the mortality in the 18,992 home births was nearly as low as that in the English populations, and that, if the rate had been only the same, one in 168, in the Rotundo, 58 less would have died in it, or, if only one in 136 had died there, as in the Coombe, only 29 would have died, and 53 lives would have been saved.

2. The published reports of the Board of Superintendence of Dublin Hospitals show that, in the ten years ended March, 1867, there were 17,605 births in the Dublin lying-in hospitals, and that 426, or one in 41, died in childbirth in them. 12,714 of these births were in the Rotundo, where 364, or one in 35, died; 4891 were in the Coombe, where 60, or one in 81, died. 215, or one in 60, births died of puerperal fever in the Rotundo, and 29, or one in 168, died of it in the Coombe. 153, or one in 83 births, died of the "accidents" in the Rotundo; 31, or one in 157, died of them in the Coombe. Now, if the mortality in these 17,614 hospital births had been only the same (one in 168) as in the 18,992 home births in the same district in the three years ended 1866, 321 lives would have been saved in these ten years, as only 165 would have died; or if the rate of mortality in the Rotundo had only equalled that in the Coombe (one in 81 births), 228 less would have died in the Rotundo. But, if only one in 184 had died, as in England, 330 lives would have been saved.

3. The printed Abstract of the Rotundo Lying-in Hospital shows that, from 1758 to 1864, both years inclusive, 182,179 births took place in that institution. On a rather laborious examination and analysis of this important document (which gives the births and deaths for each year) I find that, in 49 of these years, not successively, but at intervals, the mortality averaged one in 142 births—the highest in a year being one in 102 births, the lowest one in 223. In the 58 other years, the proportion of deaths to births averaged only one in 51. In the 49 years, there were 90,444 births, and 635 died; in the 58 years there were 91,735 births, and 1797 died, and the mortality in these years ranged from one in 99 births in one year to one in 13 4-51 in another. It is remarkable that, during the eleven years ended 1864, the mortality in the Rotundo in any year has not been lower than one in 66 births, and in the three succeeding years (1865-7) 100, or one in 37, died in the Rotundo, out of 3713 births.

Now, if only one in 184, as in England, had died in the Rotundo in those 58 years, 1293 lives would have been saved, or even if the death rate had been only the same as in the 49 years (one in 142), 1151 less would have died; and coming to the last fourteen years, if the mortality had been only one in 142, there would have been a saving of 247 lives in that time.

This high mortality is not confined to the Rotundo Lying in hospital; it is reported to have been even higher in those of Paris (one in 18½), in Vienna (one in 25½), in St. Petersburg (one in 26), in London (one in 31), &c., and in all is chiefly attributed to puerperal fever. For instance, in 1862, 39 or 40 women died of that disease in the Rotundo, 2 of typhus fever, 4 of pyæmia, and 11 of scarlatina: in all 80, or one in 12¼ of the births, died. In 1863, 3 died in it of typhus fever, 2 of pyæmia, 3 of scarlatina, and 30 of puerperal fever; of 41 that died, only two or three could be attributed to the accidents of child-birth. The year's mortality was one in 25½ births. Adverting to this, Mr. Simon reports to the Privy Council, that—"the outbreak furnishes an example of the well-established fact that scarlatina, typhus, and other exanthemata, are not only peculiarly apt to attack puerperal women exposed to their contagious influences, but prove peculiarly fatal to them, and that these poisons constitute a fruitful source of contagious forms of the so-called puerperal fever."

A remarkable instance of the havoc which puerperal fever causes in Lying-in Hospitals, is given by one of the Rotundo Assistant Masters in THE MEDICAL PRESS AND CIRCULAR of the 3rd October, 1866. He states—"During the month of March, 117 cases were delivered and five died. In April, a woman who had been confined the day before, died. In the same ward with the last patient were four others, three of whom were attacked, all died; none of them living more than 12 hours. Thus, out of a total of 25 patients who were in the lying-in wards at the time of the outbreak, 17 were attacked, and 16 died. It is the custom in this hospital to have patients suffering from this disease in the same ward with others; in fact, we never remove them until we anticipate a fatal termination."

Dr. Brishowe and Mr. Holmes, who inspected the Rotundo, subsequently reported that—"though occasional cases of puerperal fever are not uncommon in the Rotundo, epidemic outbreaks are comparatively rare." I think if these gentlemen had known that in each of 31 years the mortality in that hospital was more than one in 60 births, as I have ascertained, they would not have made that assertion, for no circumstance or disease, except puerperal fever, would be likely to cause so high a mortality in a lying-in hospital.

The mortality caused by puerperal fever in the London Lying-in hospitals has for many years induced the governors of these institutions to limit the admissions very much, and to depend more on extern maternities for affording midwifery attendance to poor women, a fact which is proved by the very small number that have died in childbirth in the London Lying-in hospitals for several years, in which only an average of about 20 died annually; Mr. Simon reports to the Privy Council that—"for the most part the lying-in hospitals in England and Scotland are small and insignificant institutions," compared with the Rotundo. Small hospitals and their extern maternities afford a far lower death rate than we have in the Dublin District. For instance,

In an excellent report on the Waterford Lying-in Hospital, Dr. Elliott states that—3458 women have been confined in it during the last 28 years, about an average of 10 each month, and that 15 women, or one in 230, died; 5, or one in 690, died of puerperal fever; and 10 of the accidents of childbirth. I may add, in proof of the value of small hospitals, that in the 11 years, ended September, 1867, there were 28,723 births in the Irish Workhouse hospitals, and that 206, or one in 139, died. This, though high, contrasts favourably with the Rotundo mortality, yet it is difficult to conceive persons more physically or mentally depressed than most of the women that are confined in our workhouses, or more likely to be affected with a contagious disease, if within its atmosphere. But as there are usually only one or two at the same time to be confined, if on rare occasions, as in the Waterford Lying-in Hospital, puerperal fever should occur, there are few or none that are susceptible of it, and the case is the same in respect to home births, and it cannot spread; but it is different when 25 or 30 women are confined at the same time in one hospital.

I beg to give two instances of the advantages of home attendance.

During the ten years ended 1867, the medical staff of the Coombe Lying-in Hospital attended 6539 extern labour cases, of whom 26, or one in 252, died. In a lately printed report by the governors and medical officers of Guy's Hospital, it is stated, in allusion to the divisions of the out-patients, that "perhaps the most interesting and most successful of these divisions is the Maternity, or Lying-in charity, as the treatment of the patients is followed up to a termination in their own homes, and we have consequently the means of arriving at data of comparison with other charities of a like description. During the last year, 1727 poor women were attended during their confinement at their own residences by pupils of the hospital, under the supervision of the physician accoucheur. The deaths amounted to four, and a nearly equal success has continued to mark the progress of the department since its first organisation" (which occurred ten years ago). "In this respect, its working contrasts favourably with the experience of public institutions where women are admitted for the purpose of being lodged during their confinements, but where they are so liable to suffer from occasional outbreaks of puerperal infection."

Greatly to their credit, the governors of Sir Patrick Dun's Hospital have lately established an extern maternity charity, and have at much cost provided a residence for an assistant to their midwifery professor, Dr. Sinclair. Under this assistant, the medical students of Trinity College learn practical midwifery by attending poor women in the district of St. Mark's parish and Ringsend. They have also appropriated some hospital beds for the treatment of the particular diseases of women, and have established a ladies' committee, by which some tea, sugar, and baby-flannels are being given to such poor lying-in women as are found in need of them. These judicious and humane arrangements will provide for a population of about 23,000, and if somewhat similar arrangements were made for the remaining population of the city, about 230,000, some lives would be saved every year, and many poor women would be assisted in their hour of need. I believe there are *ample means and materials to make these provisions or arrangements*, but I must not trespass further on your space.—Yours, &c.,

DENIS PHELAN.

22nd August, 1868.

Gleanings.

CUPPING GLASSES IN THE TREATMENT OF ANTHRAX.—M. Foucher adopted the following method of treating a case of anthrax. It was as large as an egg and situated in the left dorsal region, on a level with the spine of the scapula. He procured a cupping glass about an inch and a-half in diameter, and adopting to it the pump, he placed it over the carbuncle and exhausted the air. The cup filled quickly with sanious pus and shreds of tissue; he left it on for some moments, when upon taking it away the pain disappeared and the tumour was emptied of its contents. He applied the cup three successive days; each time all organic detritus was removed from the tumor, and the third time the integument over the part came away, leaving a healthy exposed surface, perfectly clean, and commencing to be covered with healthy granulations. The borders of the wound were irregular, sharp, and elevated, and suppuration was normal. The dressing consisted of poultices, and the wound proceeded to a speedy cure.—*Benchordat's Annual Abstract.—Pacific Med. and Surg. Journal.*

A CASE OF PUERPERAL CONVULSIONS.—A stout negress was taken in labour, and in an hour, without any apparent cause, was attacked with violent spasms. The membranes were unruptured, the vertex presenting, and the pelvis was roomy. The diagnosis was made that the convulsions depended on an "erratic distribution of nervous energy." The membranes were ruptured, but the uterus was not competent to expel the fœtus. The convulsions were somewhat abated by the use of chloroform. After waiting some time, it was decided to use hypodermic injections of morphia, and accordingly, half a grain of the sulphate was injected under the skin, on the arm. In less than five minutes, the effect of the narcotic was plainly perceptible in its controlling influence on the convulsive respiration, and the uterus began to work more vigorously, and in ten minutes the child was delivered. The convulsions after delivery recurred only at long intervals, and the mother and child did well.—J. C. OSBORNE, M.D., *in New Orleans Journal of Medicine.*

LIME INHALATIONS IN CROUP.—Dr. B. B. Wilson of Philadelphia, reports in the *Richmond and Louisville Medical Journal*, the successful treatment of two cases of croup by "lime inhalation," one of which he says, was undoubted "pure and uncomplicated membranous croup." It had existed several days, and was in a most critical condition when first seen and prescribed for. The doctor claims for the inhalation of "the vapour of lime" that in addition to being "an efficient remedy for such a desperate phase of disease . . . it can be used in addition to, and without interfering with any other treatment. . . . There can, therefore, be no objection to its exhibition in cases in which the prognosis is most unfavourable, and it is in those cases particularly that I desire the profession to give it an opportunity to prove its value. . . . . It can be conveniently administered by slacking in a pitcher a lump of quick-lime, as originally suggested by Dr. A. Geiger, of Dayton, Ohio, a vapour bath being extemporized by two or three large quilts or blankets, supported by chairs or props, the head-board of the bed, or arm of the sofa, and including the entire body of the patient within its limits.

AN INTERESTING CASE OF LABOUR.—N. Gulman, M.D. (St. Louis *Med. Reporter*) communicates the following interesting case of labour. He was called on April 6 to a primipara, aged 21. After a protracted labour she was delivered of a male child, after passing eight hours in gestation. He called the next morning after delivery, and was told that she had convulsions about four o'clock in the morning, and had had a paroxysm every half hour. After waiting at the bedside about five minutes, the patient went into a convulsion, of which she had a warning. The spasmodic movements always commenced about the legs and arms first; the convulsion, which was of an epileptic form, lasted about five minutes, and then the patient fell asleep, which lasted about ten minutes; then she roused up and remained in a semi-conscious condition until another paroxysm returned. Pain in the frontal region was her chief complaint.

Blood-letting was decidedly indicated, and he proceeded to take from the arm 16 to 20 ounces of blood. The following prescription was also ordered:—

℞. Hydrarg. chloridi mitsi, gr. xvj.
Pulvis jalap. optim., gr. xxv.
M. Ft. Chart. No. 5.

Of which she took one every half hour. A few hours afterwards he took another medical man with him, and the patient was found comatose, with stertorous breathing; the bowels had not moved. The pulse was found strong and forcible. By the advice of Dr. Cooper, who thought that the only hope for life was in bleeding, ten or twelve ounces more blood was taken, which made a decided impression on her pulse. With careful nursing, her recovery was rapid and complete.

He reports this case to draw the attention of the profession to these cases of disease, which require prompt and efficient treatment. He did not use opiates, anti-spasmodics, or anæsthetics, as are usually recommended, because he believes that the disease is nothing more nor less than a congested state of the brain, and probably the spinal column.

He states in conclusion, that this case did not present very well marked indications for the use of the lancet, but it was well borne. She had diarrhœa up to forty-eight hours previous, and still he gave her alterative doses of mercurials, with strong purgatives; no anodyne medicine was taken.

TREATMENT OF A SEVERE CASE OF WHOOPING-COUGH BY VACCINATION.—A very severe case of whooping-cough occurred in a child sixteen months old. The paroxysms varied from twelve to fourteen a-day. With the idea of cutting short the malady, or of modifying its severity, the child was vaccinated. Upon the first appearance of the areola, and before the full development of the vesicle, *all* convulsive coughing had ceased. A. Aronstein, M.D.—*Pacific Med. and Surg. Journal.*

LACTATE OF ZINC IN EPILEPSY.—Dr. Hart has tried this remedy in combination with belladonna, on 240 patients in the Western Lunatic Asylum of Kentucky, all of whom had been affected with epilepsy from three to six years. An improvement took place in all, and in no case did he use it without effectually controlling the paroxysm in from 24 to 48 hours. His formula was:—℞. Zinci lactatis, gr. xxx.; ext. belladonna, gr. viii. M. ft. pil. x. Sig. One before each meal. It is a question which remains still to be decided, what is in fact the best remedy for this dreadful affection. The whole family of zinc salts and its oxide have, as well as the lactate, been highly recommended by different parties for curative virtues in convulsive nervous diseases. The sulphate, Dr. Babington had good success with in treating epilepsy, but the valerianate was considered the most effective of all the zincs in doses of one-half a grain raised gradually to three grains three times a-day. The extract of belladonna is frequently united with the zinc in pill, and it may be supposed, from its general use, that it has some peculiar sedative action in convulsive disease. The bromides at present, however, seem to have the most popular and promising position.—*Med. Archiv.*

HYPODERMIC USE OF MORPHIA DURING ANÆSTHESIA.—In a recent clinical lecture, connected with the operation of Lithotomy, Prof. Wm. Warren Greene, of the Maine Medical School, said that he was thoroughly convinced that the use of warm, instead of cold sponging, diminishes very much the shock in this, and other severe operations, and also the liability to inflammation. The water should be fully up to blood heat, and the part should be kept as near its natural temperature as possible during the operation. The cases where this indication is over-balanced by the necessity for the styptic effect of cold are comparatively rare. A second point was the importance of the subcutaneous injection of morphine *while the patient was under the influence of ether.* The influence of this early and speedy introduction of an anodyne into the circulation, in anticipating all pain and irritation and preventing shock, can hardly be over-estimated, especially after severe procedures and in feeble subjects. But another effect, of the greatest consequence, as regards at least the comfort of the patient and the convenience of all parties, is the decided effect of morphine thus introduced in shortening the anæsthetic influence *and in preventing delirium and nausea.* He is in the habit of giving a *full* dose—usually not less than half a grain and often a whole grain—and is quite sure that a trial of it is all that is necessary to secure its adoption by surgeons everywhere.—*Medical Gazette.*

◆

Medical News.

THE PUBLIC HEALTH.—In the week that ended on Saturday, August 15, 4141 births and 3573 deaths were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 29 per 1000 persons living. The annual rate of mortality was 24 per 1000 in London, 27 in Edinburgh, and 26 in Dublin, 25 in Bristol, 36 in Birmingham, 36 in Liverpool, 44 in Manchester, 42 in Salford, 34 in Sheffield, 32 in Bradford, 36 in Leeds, 34 in Hull, 31 in Newcastle-upon-Tyne, and 29 in Glasgow. In ten large English towns, including London, the annual death-rate from diarrhœa last week was 7 per 1000 persons living, against 9 and 8 in the two previous weeks. In the several towns it was 4 in London, 5 in Bristol, 6 in Newcastle, 9 in Bradford, 10 in Sheffield, 11 in Hull, 12 in Liverpool and Manchester, 14 in Salford and Leeds, and, again highest, 17 per 1000 in Birmingham. Although the deaths from diarrhœa showed a considerable further decrease in London, they were more numerous in most of the provincial towns, and the 779 deaths referred to this cause in the ten towns were only 17 below the number in the previous week. The deaths registered in London during the week were 1462. It was the thirty-third week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1425. The deaths in the present return exceed by 37 the estimated amount, but are less by 83 than the number recorded in the preceding week. The deaths of 223 children and 22 adults from diarrhœa were recorded. Cholera or choleraic diarrhœa proved fatal to 19 children and 10 adults. The mortality from diarrhœa exhibits a decrease, but the number of deaths from cholera was the same as in the preceding week. The necessity for prompt and active treatment of these diseases in the earliest stage cannot be too generally known. Many lives would be saved if medical aid were obtained at the onset. The mortality from diarrhœa and choleraic diarrhœa or cholera in the London waterfields to 100,000 living was 7 in the New River, 8 in the Grand Junction, 11 in the Southwark and Lambeth, 12 in the East London, and 10 in the Kent field of supply. The deaths of 3 persons from sunstroke were recorded last week; in the three preceding weeks 11, 6, and 4 fatal cases were registered. At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·630 in. The barometrical reading decreased from 30·01 in. on Sunday, August 9, to 29·34 in. on Thursday, August 13. The mean temperature of the air in the week was 64·3 deg., which is 2·4 deg. above the average of the same week in 50 years (as determined by Mr. Glaisher). The highest day temperature was 82·7 deg., on Monday, Aug 10. The lowest night temperature was 52·0 deg., on Friday, August 14. The mean degree of humidity of the air was 71, complete saturation being represented by 100. Rain fell to the amount of 0·37 in., of which 0·13 in. fell on Tuesday, 11th August, and 0·23 on Thursday, 13th August. On Tuesday, 11th August, the rainfall at Hull amounted to 1·22 in., at Wakefield to 0·80 in., and at Eccles to 0·72 in. The general direction of the wind was variable. Ozone was observed on six days during the week.

SCOTTISH REGISTRAR-GENERAL'S QUARTERLY RETURN.—The return just issued records 16,928 deaths registered in Scotland during the second quarter of the present year, being in the annual proportion of 21·2 per 1000 of population, or one per 1000 below the average of the last ten years. In the town districts the mortality was at the annual rate of 25·2 per 1000, while in the country districts it was 16·4. The mean death-rate in the previous ten years in the former was 25·6, and in that of the latter 17·7, so that the influence of the mild weather in Scotland during the quarter under review was more favourable in the country than in the town districts. The weather was unusually mild over all the lower portions of Scotland. The rainfall was very nearly the average, though greater than usual during April and May, and correspondingly below the average in June. Acute pulmonary affections were less prevalent and less fatal than in former years, and the ordinary epidemics had not been more prevalent than usual. Whooping-cough was the most fatal epidemic; scarlet fever was the next most fatal disease in the most southern part of Scotland, while measles was very prevalent in the northern parts. Typhus and enteric fevers maintained their normal prevalence; the proportion of deaths from typhus was about double that from enteric fever. The deaths from consumption were, if anything, rather higher than usual, nothwithstanding the mildness of the season. The mean temperature of April, with 5754 deaths, or 192 daily, was 46 deg.; that of May, with 5665 deaths, or 183 daily, was 51·4 deg.; and that of June, with 5509 deaths, or 183 daily, was 55·6 deg. The mean temperature of the quarter was 51·0 deg. The mean rainfall was 6·96 inch. The births registered during the quarter numbered 31,025, or the annual birth-rate of the season was 38·9 per 1000 of population, the average rate being 37·8 per 1000. The marriages numbered 5660, or 7·1 marriages per 1000 persons living; the average rate being 6·9 per 1000. If a high marriage-rate may be taken as an indication of prosperity, then in a commercial point of view the eight principal towns of Scotland arranged themselves during the quarter as follows:—Thus, of every 10,000 persons in each town there married 71 in Paisley, 76 in Glasgow, 80 in Greenock, 88 in Aberdeen, 103 in Perth, 106 in Leith, 109 in Dundee, and 118 in Edinburgh.

THE CONDITION OF THE THAMES.—The *Field* says:—The old fishermen—"trinkermen" as they are termed—in the tidal way are praying devoutly for a continuance of rain, as they declare that if a very large bulk of water does not fall between this and the set of the approaching spring tides a fish of any kind will not be left in the river from Putney to Kew. The captains of the river steamers likewise state that they do not recollect so great a stretch of mud deposit for years past as is now to be seen at low water from Chelsea, past Wandsworth on both sides, up to Bishop's Palace at Fulham. The low tides have disclosed the existence of many a covert pipe ingeniously concealed and as persistently denied; but, of course, now their presence is manifest, these suspicious ducts will be declared to be used only for taking the water into the works, and not for the egress of wash and other deleterious refuse. We shall perhaps hear more about some of these questionable pipes. Gudgeons have shown themselves as low down as Chiswick, but unfortunately on the top of the water, from whence they have been removed by scoop nets—now the common implement of every little mudlark upon the banks. It would be cheering to hear that an inspection of the several creeks up the Thames was to take place. An investigation faithfully carried out would reveal a good deal that is interesting. A visit to the pools in the upper reaches shows how extremely low they can be without being perfectly dry. There is but a mere trickle over some of them, yet it is stated that "the supply for London of the water companies located at Hampton has not fallen off," and that "there is a resource for double the demand if needed." This is a statement of serious import to London; may it be true! It would be, therefore, interesting to ascertain from whence this supply is derived and kept up? If the pools above have ceased to send their usual flow below, there must be some hidden springs, not hitherto taken into the calculation of our water supply, to account for this seeming contradiction. Should such be the case, a matter of very considerable anxiety—not only during droughty seasons but with an ever-increasing population to provide for—is in a measure mitigated.

THE Director-General presents his compliments to the editor of THE MEDICAL PRESS AND CIRCULAR, and begs to enclose, for insertion, a list of gentlemen who competed successfully for appointments as assistant-surgeons in H.M. British Medical Service, at the examination held at Chelsea on 10th August, 1868.—Army Medical Department, August 22nd, 1868.

1. J. Chatterton, 2210; 2. A. H. Stokes, 2160; 3. G. Corry, 2055; 4. W. H. Saunderson, 1950; 5. J. J. Crean, 1915; 6. J. Scanlon, 1900; 7. F. G. Adye-Curran, 1875; 8. T. Faris, 1855; 9. G. R. Triphook, 1780; 10. H. Stannard, 1745; 11. J. H. Webb, 1730; 12. W. Sharpe, 1725; 13. R. D. Bennett, 1695; 14. H. E. Maunsell, 1670; 15. J. G. Thornley, 1655; 16. A. W. Duke, 1630; 17. T. E. Carroll, 1600; 18. F. A. Davy, 1585; 19. H. B. White, 1560; 20. R. M. Bradford, 1530; 21. E. C. Maxwell, 1530.

A ROYAL decree in the *Gazette* of Madrid orders quarantine to be enforced on arrivals from England.

DR. NELATON, the eminent surgeon, has been made a senator. This is the first time that an "operative" representative of the medical profession has been promoted to a seat in the Upper Chamber of the Luxembourg. It was Dr. Nélaton, as your readers may remember, who extracted the ball from Garibaldi's ankle after the Italian campaign. It is little probable, as the *Avenir National* slyly remarks, that this cure had anything to do with his being raised to the dignity of senator.

MADAME ALEXANDRINE BRIS has just passed a brilliant examination before the Faculty of Sciences at Paris and obtained the degree of Bachelor. Her intention is to study medicine with a view of obtaining a physician's diploma.

SURGICAL SEPARATION OF THE SIAMESE TWINS, CHANG AND ENG.—The scientific world, and especially that portion of it who have made the study of medicine and surgery their profession, cannot fail to be intensely interested in the fact which has recently come to our knowledge, of the determination of Chang and Eng, the Siamese twins, to submit to a surgical operation for the purpose of dissevering the wonderful link that has so long bound them together. Some forty years ago these twins were introduced to the notice of the civilized world, having been brought to England from Siam in the year 1827 or 1828, by Captain Bunker, at present living in New York; and for a series of years they were exhibited to the public at all the great centres of civilisation. Having visited America, they determined to make this land their home. They bought a valuable tract of land in North Carolina, married two sisters, and settled down in the ordinary routine of a farmer's daily life. Each of them is now the father of nine children. The reason for their determination, at this late day, to call in the art of surgery, to produce an entire physical separation, is that having reached such an advanced age (59 years) they are fearful that one may become the subject of disease which may prove fatal to both. The interesting question arises, what are the probabilities of a successful operation being performed? It will be remembered, in pursuing these inquiries, that the twins are held together by quite a massive link of thoroughly normal and perfectly vitalised integument, some ten or twelve inches in circumference, situated near the vital organs, and in close proximity to the heart and lungs, and the connection is so intimate that each seems to be thoroughly an organised portion of the other, as much so as any of the ordinary members of a naturally constituted human body. Sensation, nervous impression, mental phenomena, morbid, physical, and nervomental conditions, all show a most perfect psychical unity in this wonderful dual physical existence. The question in regard to the result of an operation is no new one, but soon after their first appearance in London and Paris it excited the minds of the foremost intellects in the surgical world. If we remember rightly, the "Twins" were exhibited before the Academy of Physicians and Surgeons in Paris at that time, for the purpose of ascertaining their opinion in regard to the probabilities of a successful operation. The disagreement in regard thereto, we believe, led to the abandonment of the project. Has the science of surgery so rapidly advanced that to-day successful results can be promised when there was so much doubt a score or two of years ago. We understand they contemplate visiting Paris for the purpose of having the operation performed.—*New York Tribune.*

THE VICTIMS OF THE ABERGELE CATASTROPHE.

From a medical point of view the circumstances of this most painful occurrence leave very little for us to record. Unhappily there was no mitigation in the severity of the injuries; no medium between the utter destruction of the unfortunate sufferers who were burned, and the contusions of slight significance which the other passengers received.

We believe that the most serious non-fatal casualty was a temporary concussion of the brain, and both the driver and guard concur in the belief that the shock of the collison was comparatively so slight, that were it not for the fire there would, probably, have been no fatality whatever. The most extraordinary point in the whole misfortune was, that not the least sound or outcry was heard from the persons in the foremost carriages. It is totally impossible to suppose that the occupants were everyone rendered insensible by the shock, though hardly any of the other passengers suffered to that extent. It is also manifestly impossible that the victims can have been overpowered by the fire before they had time even to utter a cry. We believe the explanation must be looked for in absolute and instantaneous suffocation, or anæsthesia by the vapour of the petroleum, a supposition, which we would fain hope may be correct.

Petroleum consists of various hydrocarbons of various boiling and vapourising points. The more volatile ones were extensively used during the American war, under the name of turpentine substitutes. The *vapour* of these will form *explosive* mixtures with atmospheric air. After them come the portions that are used for burning in lamps. They are not explosive with air, but highly *inflammable*, particularly when they have an absorbent material, such as dry earth, wood, &c., to burn upon. The heavy oils are not so inflammable, and are only used for lubricating. Keroselene—the most volatile portion, and which only constitutes a very small percentage—has been used successfully as an anæsthetic, and is similar to benzol or æther in its effects.

Without attributing anæsthetic results, which the percentage of keroselene would not justify, we may still hope that the instantaneous volatilisation of a great quantity of this petroleum may, as in the case of nitrous oxide, by simply depriving the lungs of the air, have caused the immediate anæsthesia which we know by experience would result from such a contingency.

The interval from perfect consciousness to total insensibility is, as we know, almost inappreciable, and it is easily supposable that, for the instant, the shock of the collision may have completely incapacitated the sufferers from even a cry.

NOTICES TO CORRESPONDENTS.

Proofs reaching authors in England on or before Friday morning are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper only.

All Communications and Letters must be authenticated by the name of the writer, though not necessarily for publication.

To Contributors.—It would save both time and trouble if gentlemen would write name and address at the back of their MS., to insure an early transmission of proofs.

Papers have been received on Cannabis Indicis in Catarrhus Senilis; Veratrum Viride in Pericarditis; Belladonna in Infantile Icterus.

Lord Amberley on Over-population.—A correspondent informs us that Lord Amberley denies the accuracy of our report of the proceedings of the Dialectical Society, published in our impression of July 22nd, at the same time calling upon us to verify our report. To this request we are happy to comply, as the gentleman who represented us at the meeting, upon reference to his notes, informs us that the report is strictly correct. The wording may be somewhat different, but the meaning conveyed by the several speakers was unquestionably that recorded in our columns.

Mr. J. Waring-Curran, Spalding.—Your proof was returned through the post, "Insufficiently Addressed." Please write name and address legibly at the back of any communication intended for the printer, that proofs may not be delayed or miscarry.

Dr. Davey, Bristol.—Your letter shall appear in our next.

Mr. S. B., Plymouth.—The subscription in advance, post free, is 21s. 8d. It can date from any time most convenient to yourself.

Dr. G. F. Burder is thanked.

The Disaster at Abergele.—Dr. H. C. Andrews, has just issued an appeal to the benevolent, on behalf of the widow and eight children of the late head-guard, Smith, who was amongst the sufferers from this fearful accident. From personal experience, we are happy to add our testimony to that of Dr. Andrews, as to the kindness and attention at all times shown by this poor man, especially to invalids; and we hope the appeal now made will place his distressed family above the pale of want.

Erratum.—Letter on Puerperal Fever, p. 193, twelfth line from bottom of column, read 14 instead of 13 4-51.

HEDGES AND BUTLER,
155, REGENT-STREET, LONDON,
And 30, KING'S-ROAD, BRIGHTON.

KINAHAN'S LL WHISKEY.

DUBLIN EXHIBITION, 1865.

This celebrated Old IRISH WHISKEY gained the Dublin Prize Medal. It is pure, mild, mellow, delicious, and very wholesome.—Sold in bottles at 3s. 8d., at the retail houses in London; by the Agents in the principal towns in England; or, wholesale, at 8, Great Windmill-street, London, W.—Observe the Red Seal, pink label, and cork, branded "Kinahan's LL Whiskey."

MOST IMPORTANT TO FAMILIES.

GUINNESS'S XXX PORTER.—J. Bebe invites attention to this Celebrated Porter in Bottle, being now specially ordered to invalids, for its nutriment and strengthening qualities, in fact it has been found, in great many instances, to supersede Wine in recruiting health and strength. Each Bottle is wired and tin-foiled. and is protected by his label and "Trade Mark." Prices are as follows. Terms Cash.

	Per doz.
Guinness's Celebrated XXX Porter (small bottles)	... 2s. 4d.
Guinness's Celebrated XXX Porter (large do.)	... 4s. 6d.

Ten Vans deliver daily in the city and suburbs, and orders sent by Railway to all parts of Ireland.

JOHN BEBE, Rectifying Distiller, Direct Wine and Brandy Importer,
18, THOMAS-STREET, DUBLIN.

Aerated Lithia Water.—Messrs. BLAKE, SANDFORD, and BLAKE, are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. Garrod's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA.—Also, Potash, Citrate of, Potash, Soda, Seltzer, Vichy, and Mineral Acid Waters, as usual.

Blake, Sandford, and Blake, Pharmaceutical Chemists, 47, Piccadilly.

A. & R. THWAITES & CO.,

PREPARERS AND IMPORTERS OF
MINERAL WATERS
TO HER MAJESTY,
57, *UPPER SACKVILLE-STREET, DUBLIN.*

SINGLE AND DOUBLE SODA WATERS,

Prepared in Cisterns of Granite.

THESE Waters were introduced to the notice of the Public in the year 1800, as their invention, by the testimony of the Professor of Chemistry (*the late ROBERT PERCEVAL. M.D.*), in his Lectures in Trinity College, Dublin, and from that period have continued to obtain the recommendation of the Gentlemen of the Medical Faculty, and the approbation of the Public.

The Double and Single Soda Waters derive their names not from the quantity of fixed air which they contain, but from the peculiar mode of preparation employed by A. & R. T. and Co., which renders them highly useful to the powers of digestion, improving the appetite, and stimulating the hepatic functions.

The above kind of Soda Water is exclusively prepared by them, and is not manufactured by any other House in the Kingdom.

SCHWEPPE'S MINERAL WATERS. By Special Appointment to Her Majesty and H.R.H. the Prince of Wales. Every bottle is protected by a label having name and trade-mark.—London, Liverpool, Derby, Bristol, Glasgow, Malvern.

THREE PRIZE·MEDALS—[Paris Exhibition, 1867.]

CROSSE AND BLACKWELL,

Purveyors in Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared, that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles, and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloater Pastes, Strasbourg and other Potted Meats, and Calf's-foot Jellies of various kinds for table use. C. and B. are Sole Agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstair's Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE & BLACKWELL, 21, Soho-square.

WHEAT PHOSPHATES IN CHILDREN'S FOOD.

MESSRS. CHAPMAN and CO. beg to call the attention of the Profession to their "PREPARED ENTIRE WHEAT FLOUR," which, in addition to the Starch, contains all the Gluten and Phosphates of the Grain, thus rendering it far more valuable than any of the ordinary foods now in use, and is equally serviceable for Puddings, &c.

Sold by all Chemists, at 3d., 6d., 1s., and 3s.—St. James' Steam Mills, Hatcham, S.E.

DIABETES.

BONTHRON'S DIABETIC BREAD AND BISCUITS

Have been approved by the Profession and by Diabetic Patients; contain no starchy matter, and are highly palatable and agreeable.

Country Orders punctually attended to.

Address, J. BONTHRON, 106, Regent-street, London, W.

EFFERVESCING

COMPOUND CITRATE OF POTASH WATER.

IN a Series of Lectures on Gout, Rheumatism, Rheumatic Gout, and Sciatica, published in the *Lancet* by Dr. Fuller, attention was drawn to the extraordinary virtue of Citrate of Potash in neutralising the acid products of indigestion and in ridding the blood of the uric acid and other acid materials. In confirmation of this opinion Dr. Roberts, of Manchester, in an admirable paper published in Vol. XLVIII of the "Transactions of the Royal Medico-Chirurgical Society of London," proves, by a series of elaborate experiments, that the solvent power of Citrate of Potash in gouty urinary deposits exceed that of Lithia and all other alkalies, and when combined with certain materials calculated to correct acidity, proves the most valuable of antacid and gouty remedies, neutralising the acid which exists in the blood, and preventing its being passed through the kidneys in the form of gravel. It is very agreeable and refreshing. Two or three bottles may be taken daily.

Prepared only by W. TWINBERROW AND SON,
2, Edward-street, Portman-square; and 45, Westbourne Grove,
London, W.

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION: THEIR DIAGNOSIS AND TREATMENT.

By S. SCOTT ALISON, M.D. EDIN.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

No. V.

IN cases of disorder of the cervical portion of the air-tube apparatus simulating pulmonary consumption, the careful application of the tests of physical exploration suffices to declare with all but certainty in every case the true nature of the malady, and the comparative safety of the patient.

In the first place, a large body of negative evidence is procured by the examination of the chest—none, or very few, of those signs being present which we find in pulmonary consumption. Except in a few examples of simulated pulmonary consumption, percussion gives the clear, long-continued resonance of healthy, or of more than usually air-holding lung, and it is symmetrical. The motion is ample, and except in very exceptional cases, such as those combined with malformation of the chest, or old pneumonic or pleuritic condensation, it also is symmetrical. The humid crackle in the apices of the lung is absent, except in a very few cases of liquid bronchitis, the value of which is usually to be made out by the presence of more or less sibilus or bronchitis, and the absence of dulness on percussion. Chamber or cavity sounds are not commonly to be discovered, but it must be admitted that, in a few exceptional cases, air-chamber sounds, with loud noise and air-chamber crackling, are to be discovered in throat affections, not combined with tubercle of the lung, but this is a very rare occurrence. When these signs are made out, the throat affection is combined with bronchitis and emphysema, and with dilatation of one or more of the chief bronchi, in these cases the percussion being clear, over clear, and sibilant and sonorous rhonchi, or wheezing, being present throughout the chest, generally with comparatively little emaciation of the body, the bronchial character of the malady is indicated. The presence of diseased heart supports the non-tubercular view—organic disease of the heart is meant.

It is also to be admitted that throat affections, simulating phthisis, or tubercle of the lung, are met with, but as extreme rarities, in which the throat affection is combined with consolidation of the lung, the result of pneumonia, a cirrhose state in which the voice becomes very loud above, and simulative of the cavernous character, in consequence of the contracted and pressed-upon air-tubes below refusing to *disperse* the voice as usual throughout the lung structure, causing reverberation above. The heart is often displaced more or less, especially at its base, in consequence of the traction of the contracting lung giving rise to undue loudness, and to undue impulse at unwonted parts of the chest.

In examples of throat disorders simulating pulmonary consumption, I regard as a very valuable piece of negative evidence of the non-pulmonary tubercular character of the malady, the absence of an auscultatory sign I have very frequently discovered in cases of the early and yet scanty deposition of tubercle in the apices. I refer to an interrupted or divided friction-like sound or rhonchus. The sound is coarse, and three or four or five divisions, well-marked, are made out in a single inspiration. It resembles the sound of two pieces of coarse cloth slowly rubbed upon each other in contrary directions. The motion not being continuous, the sound is interrupted. Its *locale* is usually one shoulder; it is sometimes found at both. It is heard best above, between the scapula and the clavicle; at the scapular region; and it is sometimes most audible at the head of the humerus. It does not proceed from pleural friction, but from the repeated obstructions to the passage of the inspired air-column through the finest bronchial tubes, from the pressure of tubercular material.

This sound, to which little attention has been paid, is sometimes mixed with the well-known click and fine, humid, distinct crackle of early phthisis. This sign is very inconstant: heard now, it may be inaudible in a few minutes. It may continue for days, then stop for hours, but to return with certainty, and remain with slight intervals until the tubercular deposit shall be absorbed or become softened, and give rise to cavernules and cavities. The presence of this auscultatory sign, and its amount, are a good deal affected by the quantity of the secretion of the mucous membrane of the fine bronchial tubes, and in consequence the sound under consideration varies considerably with the state of the weather, and with the varying amount of watery vapour in the atmosphere. I have found this interrupted, coarse, friction-like sound to become more marked during the prevalence of cold, dry winds. When this sound has disappeared in the breaking-down lung, it is often heard in the apex of the opposite one, usually regarded as healthy, but now really becoming the seat of tubercular deposit. For some years I have called attention to this important sign, at the Consumption Hospital. I regard the *absence* of it in throat affections simulating pulmonary tubercle as a very important piece of negative absence. Its presence I hold as very suspicious in respect of the lung, and its permanent absence as a very material fact in support of the disorder of the patient being one chiefly of the throat or its adjacent parts. It is for these reasons I have thus dilated upon it in this place. I do not mean to say that this sign is necessarily associated with tubercle, but it is almost always so associated.

In examples of throat disorder simulating pulmonary consumption, while auscultation applied to the chest affords most valuable evidence of the absence of signs observed in tubercle of the lung, with the exceptions already stated, and more particularly of the coarse tube blowing inspiration and expiration likewise unduly prolonged. Applied to the neck it gives positive and readily appreciable testimony of the presence of disease in the upper part of the air-tube apparatus, in the forms of altered respiration sounds, adventitious sounds, and of alterations of the voice.

The most common form of alteration of the respiration in the upper part of the air-tube apparatus is a high-pitched constrictive quality very easily recognised, and seated, according to the locality of the disease, at the glottis, at the larynx, or the narrows of the trachea, immediately above its bifurcation. The constriction sound pervades all parts, but it is most intense where the disease is immediately located, and the greatest intensity is, as respects locality, ascertained with perfect ease by the use, simultaneous or successive, of the two limbs of my differential stethoscope. The most intense constriction is heard in that ear connected with the immediate seat of disease. In cases of severe constriction sound of the trachea some degree of constriction sound is also heard at the upper part of the sternum and under the clavicles; but the origin of the sound is proved to be in the throat, and not in the lung or chest by the ear connected with the limb of the differential stethoscope, again connected with the *throat* having the constriction sound in its louder degree.

This constrictive condition of respiration sound is heard all over the neck, from the hyoid bone above to the upper border of the sternum below in front, from the inferior angle of the jaw down to the scapular extremity of the clavicle at the side, and from the lower part of the occiput down to the second dorsal vertebra—the level of the bifurcation of the trachea, behind. In some examples of constrictive respiration dependent upon enlarged tonsils and some thickening of the mucous membrane of the glottis and larynx, the great extent to which the sound exists at the nape of the neck is remarkable, and its abatement and final disappearance, as the stethoscope is made to travel down the neck into the interscapular regions, are highly striking and instructive, suggesting that the disorder is located in the neck, and not in the chest, a point of the greatest pathological and therapeutical importance.

The duration of the inspiration and of the expiration in cases of throat disorder simulating tubercle of the lung is increased, and in some cases scarcely any pause between the sounds of inspiration and expiration and those of expiration and inspiration can be made out.

Large, moist, bubble-bursting sounds in the neck are in many examples of throat disease made out by placing the stethoscope upon the larynx or in the course of the trachea. This occurs, of course, where the secretions are in abundance, and these may be pus or mucus, with or without extravasated blood. These sounds may be heard in any part of the neck, back or front, but they are loudest at the particular seat of the disease most deeply implicated.

Small bubble-bursting sounds are also not unfrequently heard in the same parts, and these occur when the secretion is more scanty. These sounds are sometimes called crepitations, large and small. When they are heard in the course of the neck, and when they are absent in the chest, and when the respiration, the voice, and the percussion sounds are normal throughout the chest, no doubt need be felt in regarding the upper part of the air-tube apparatus as the seat of the main disease, and the local disorder there situated as the cause, for the most part, of the deteriorated general health of the patient.

In some of the more severe throat affections simulating pulmonary consumption, the respiration at the apices acquires a rough and constrictive character, and the expiration becomes long, and thus a simulation of lung disease is set up, even in respect of the auscultatory test. This occurs chiefly in cases marked by the narrowed condition of the lower part of the trachea, already fully described. Full and symmetrical expansion of the chest, long continued and symmetrical resonance on percussion, absence of humid crackling, of air-chamber signs, and of the divided friction-like rhonchus, combined with high constrictive respiration in the trachea, serve to justify the location of the disease in that part or the adjoining structures.

The stethoscope applied over the front of the neck, in many cases of disorder simulating pulmonary consumption, conveys to the ear a husky voice. Sometimes the voice is unduly resonant and loud, and this seems to arise from a moderate amount of narrowing at the glottis, and sometimes from a moderate amount of undue narrowing of the trachea, above the bifurcation.

The mechanism seems to be that reverberation of sound which obtains in *moderately* shut-in cavities or tubes, the same as we discover in narrow lanes and passages. A brazen or metallic voice is sometimes heard through the stethoscope, and this arises from a dry condition of the tube.

The cough, in many cases, heard through the stethoscope is extremely loud and explosive. Sometimes it is brazen or metallic, and this, like the voice, seems to depend upon a dry condition of the air-tube, associated with a spasmodic state. The explosion, hissing, and abrupt barking sounds, already referred to, are conveyed to the ear in remarkable force, through the stethoscope placed upon the throat.

THE FORMS OF PNEUMONIA.

By OCTAVIUS STURGES, M.D.Cantab.

Some short time since, in a paper contributed to the St. George's Hospital Reports, I ventured to suggest that for clinical purposes pneumonia may usefully be divided into four classes. I adopted the view, or rather endeavoured to illustrate and enforce it by examples—that between purely hypostatic consolidation and purely inflammatory consolidation, are to be found the great majority of cases of so-called pneumonia; in other words, that consolidation of the lung was due in most instances to the joint operation of a mechanical and a vital cause, either of these preponderating in any particular instance. It might even be possible, I have thought, by arrangement of a mass of cases, to place, in their order, the modifications in clinical respects to which the varying combinations of these two causes would successively give rise. Such a series would comprehend a complete history of the several phenomena which have been included under this common name. It would review in turn—First. That purely hypostatic consolidation, whose site is mainly determined by the posture of the patient. Secondly. The consolidation, in part mechanical, which, with a certain favouring condition of the blood, a material impediment in the course of the circulation will suffice to produce. Thirdly. The consolidation wholly due, as we suppose, to the presence of a *materies morbi*; and lastly. That inflammatory consolidation which is wont to arise in the healthy and robust under the influence of climate changes, or in response to some direct irritation.

So considered, pneumonia in some of its commonest forms becomes a mere exponent of the general state of the system, and the varying degrees of solidity which the lung exhibits under the operation chiefly of mechanical causes —now airless only, and laden with serum; and now compact, swollen, and incompressible, from a new material filling its cells, may be looked upon as conditions of the pulmonary circulation, which have their analogy in the systemic. In this view, the serous and the fibrinous dropsy which Vogel long ago described may, in the lungs, be represented by engorgement and consolidation respectively, and the two appearances, instead of being regarded as successive steps in one process, or else as arising from totally dissimilar and even opposite causes, may often be more fitly described as strictly analogous conditions, either of which may occur in any given case.

Accepting then the word pneumonia in its widest sense, I proceed to speak of the four forms of it in the order in which I have just mentioned them. As regards the first, it deserves notice, that writers who have been the most peremptory in demanding for pneumonia its true etymological meaning, do not overlook the influence of posture as determining its situation. Thus it has been sought to account for the greater frequency of right pneumonia by reference to the anatomical arrangement of the right pulmonary vessels, and even by the fact that the majority of people repose habitually on the right side. There are, indeed, some remarkable facts quoted by Grisolle, which would seem to prove that with children at least this preference of pneumonia for the right side may be at once and at will, transferred to the left by taking care that the patients lie continually on that side. In this connection must be mentioned the remarkable preponderance of double pneumonias in weakly children, and in old people; "all authors," say Rilliet and Barhez, "have recognised that prolonged decubitus on the back, inspiration of bad air, bad food, &c., have a real influence in the development of secondary pneumonia." Such patients are spoken of as having a "susceptibility for pneumonia."

Now, if it be granted that pneumonia is apt to occur owing to any cause which tends to lower vitality, and that when so occurring, its place of attack is always the most depending portion of the lung, we may either adopt the explanation of Grisolle, if it be one that "the stagnant blood sooner or later provokes a true inflammation of the pulmonary parenchyma," or we may say, more simply, that exudation into the air-cells, of one kind or another, is sufficiently accounted for by the circumstances of the case, and that the nature of it, in particular instances, will be determined by conditions of pressure and resistance, which we have no means of measuring. It is of no practical importance. It is to be observed, however, that this form of consolidation is rarely accompanied by pleurisy, and hardly ever by pericarditis, it thus differs remarkably from the pneumonia, which certain blood diseases excite in a known order of frequency. As occurring at the end of life, its only necessary condition seems to be slow dying, "the gradual withdrawal of the vital force permitting physical laws little by little to resume their sway."

Allied to these cases of purely hypostatic consolidation, which it is impossible to refer to any common cause except general failure of the powers of life, other recorded instances of hepatization are met with which seem to be due, some to a definite obstruction as in valvular disease, and others to an impediment not less real, which is offered by the altered constitution of the blood itself. But while each of these agencies plays its part in the production of hepatization, each, too, has a well-known tendency to produce the other. On the one hand, actual mechanical obstacles to the passage of the blood prevents its due arterialization, and thus render it liable to become the source of local irritation and disturbance; on the other, a hyperinotic state of the same fluid leads to the deposition of fibrin on the valves, and so in the most direct way becomes the source of permanent valvular disease. These two conditions, then, will be apt to occur together, and, so occurring, they may produce a result which either alone is insufficient to effect. Valvular disease, therefore, is not itself the cause of pneumonia. It is only the condition which determines that phenomenon in the presence of other favouring influences, themselves insufficient alone to produce it. The subjects of valvular disease may, therefore, very properly be said to have a proclivity to such attacks, just as they may be said to have a proclivity to anasarca. Consolidation of the lung in such persons may not differ intimately from that which accompanies lingering death or from that associated with blood-poisoning—either of these may have furnished its remote cause—only, here, a new source of embarrassment being superadded suffices to precipitate a result which otherwise would have been delayed, or, perhaps, by timely measures, altogether escaped.

Thus we may conceive an explanation for some of those cardiac cases in which the consolidation, though evidently depending upon blood-poisoning, yet, instead of resembling in its position the true inflammatory hepatization, occurs symmetrically at the lower and depending portions of both lungs, differing only from hypostatic consolidation in being associated with pleurisy, and often with pericarditis. In such instances the immediate cause of the exudation I conceive to be due to the condition of the blood. Its site is determined, in obedience to physical laws, where the impediments are greatest and the propelling force the least. Similarly, in cases where this rule of symmetry is not exactly preserved, we often find that hepatization in one lung is represented by extravasation in a corresponding portion of the other. In instances, especially of mitral narrowing, where the effect upon the lungs of a definite obstruction can be best studied, such extravasation occurs frequently in this association, the one appearance being about as common as the other. Thus, while it is necessary here to invoke the agency of a blood-poison, since, without it, we know that the extremest valvular contraction may go on for years, yet the lungs remain efficient, it is impossible to overlook the manner in which that agency is modified by others which are purely mechanical.

To illustrate these remarks, by reference to collected cases, it appears that in association with valvular obstruction we get hepatization of three kinds. First,[1] and most commonly, it occurs along with congestion, and resembles, pathologically, the simple hypostatic consolidation of which I have before spoken. Such cases, however, are distinguished, clinically, from these by their more rapid course, and usually by the presence of active cardiac symptoms. In some, indeed, the surrounding circumstances render it probable that the condition of the lungs is the result of the mechanical hindrance alone. Secondly, we find it—in situation again like the purely hypostatic, but now often in company with inflamed serous membranes—in cases where, together with valvular contraction, there is either a strongly-marked rheumatic diathesis, rheumatism probably being present at the time, or evidence of uræmic poisoning, or such like ground for believing that the initial cause is an altered condition of the blood. Here, too, hepatization in one lung may be represented by extravasation or congestion in the other, or the three may be mixed up together. Thirdly, and I think exceptionally, we find cases where valvular contraction and blood contamination co-existing, the latter condition overrides the other, and hepatization is met with at some defined and limited spot, as we are accustomed to see it where the valves of the heart are unaffected.

(To be continued.)

Physicians v. Surgeons.—At the Venereal Hospital of Paris one of the surgeoncies is to be abolished, and a physician is to take the appointment. Venereal diseases lie in some degree between physic and surgery. The former seems in the ascendant in the French capital. At the Lying-in Hospital a similar alteration has taken place.

---

[1] The three kinds of hepatization here alluded to I suppose to find illustrations chiefly in Class III. of my Tables in the St. George's Hospital Reports. Thus the first kind occurs in cases 1, 2, 4, 8, 12, 15, 17, 22, and 23; the second in 6, 9, 11, 13, and 20; and the third in 14, 16, 19, 21.

CASE OF STRANGULATED FEMORAL HERNIA:

EARLY OPERATION : STRICTURE UNUSUALLY TIGHT : SAC OPENED : INTESTINE VERY DARKLY CONGESTED : INTESTINAL FISTULA RESULTING : NATURAL CLOSURE OF FISTULA : COMPLETE RECOVERY.

By HENRY GRAY CROLY, F.R.C.S.I.,
SURGEON TO THE CITY OF DUBLIN HOSPITAL, ETC.

On Saturday, the 11th of July last, Mr. —— called upon me to visit his wife, who was suffering from hernia. The following is the history of the case as related by the patient on my visit:—She was 68 years of age, the mother of eleven children, and had enjoyed excellent health. Six years ago, in walking, she accidentally slipped and nearly fell, and on her return home she felt a small kernel in her right groin. She resided in the country at the time, and, on consulting her medical attendant, was advised to wear a truss, which was accordingly procured, and constantly worn during the day. The patient also stated that the greater portion of the tumour was reducible, but a small swelling always remained in the region of the hernia. Four days previously to my visit, she observed a blueness about the hernia, her bowels were constipated for several days, and on the night of the 10th of July at nine o'clock (the truss being off) she vomited. The hernia came down and became very painful. She did not attempt reduction, and says she felt unwilling to do so lest it should burst. She passed a restless night, with pain in the groin, and a burning sensation at the navel. She vomited sour fluid on several occasions during the night, and also at half-past ten o'clock that morning, half an hour before I saw her.

Symptoms at my visit.—Face slightly congested ; countenance a little anxious ; pulse quick ; patient complains of colicky pain in the umbilical region. On examining the groin, I observed a tumour occupying the region of the femoral ring at the right side, oval in shape, and about the size of a small-sized hen's egg, situated obliquely, with the smaller end upwards and outwards, in the direction of the anterior superior spine of the ilium, and the larger end downwards and inwards, towards the saphenic opening. At first glance the tumour looked like an oblique inguinal hernia, but on careful examination, I was enabled to trace Poupart's ligament, upon which the smaller end of the tumour had ascended. The patient informed me that the hernia came down originally at the upper part of her thigh, and placed her finger exactly on the femoral ring.

The hernia was extremely tense, and very painful to the touch.

Treatment before Operation.—I introduced the long enema-tube (O'Beirne's) almost its entire length, and administered a purgative injection, which was retained for some minutes. The bowels then acted, the discharge, consisting of feculent matter, afforded some relief. A grain of opium was given at once, and ordered to be repeated every hour. I informed the patient and her husband of the true nature of the case, and the necessity for early operative interference, if the symptoms were not relieved.

By 3 o'clock P.M., at which hour I again saw the patient and ascertained that she had two evacuations from the bowels since my morning visit, the vomiting had ceased, and her countenance was placid. The hernial tumour, however, was just as tense and painful to the touch as in the morning.

I accordingly decided upon immediate operation, and extemporized an operation-table, on which I placed a mattress. My friend Mr. Stokes administered chloroform most carefully (which was subsequently kept up by Mr. Florence M'Carthy), and ably assisted me in the operation, which I proceeded with in the following manner:—

The integument over the tumour having been pinched up, was divided by transfixion; the incision thus made extended from above downwards, at right angles with Poupart's ligament. Layer after layer of fascia was raised with a fine-pointed dissecting forceps, and divided on a director with a scalpel. The coverings were found to be thin, in consequence of the position of the hernia. The sac was soon reached, and a knuckle of very dark-coloured intestine appeared. A piece of omentum was observed lying to the right side of the gut, and the sac contained dark fluid.

I raised the sac cautiously with a tenaculum, and opened it, holding the scalpel flatwise. A director was then introduced, and the sac freely opened upwards and downwards. A considerable quantity of dark serous fluid escaped, which was removed by the application of a warm sponge over the wound.

A knuckle of darkly congested intestine was thus fully exposed (the size of a large walnut). A piece of omentum of pinkish hue lay to its right side. I passed my finger carefully around the gut, and detached a few slight adhesions. I next felt for the constriction, which I did with the utmost caution, lest I should injure the gut, which was unusually tense. By gently drawing the hernia downwards I was enabled to feel a tight band at the upper part of the saphenic opening (Hey's ligament). I tried to introduce the tip of my index-finger beneath the stricture, but could not do so. I accordingly bent the director near its point, and succeeded in passing it under the stricture, which I divided with the hernia-knife by cutting upwards and slightly inwards. I was then enabled to introduce the end of the little finger of my right hand, and on it the hernia-knife, and further divide the stricture. The omentum was reduced first. It passed up, beneath, and to the outerside of the intestine, which I reduced by very gentle and steady pressure. It went up with a gurgling sound. The tip of the forefinger was introduced into the abdomen, and the hernia was found to be fully reduced. One vessel, which bled at this stage of the operation, was ligatured. The wound was sponged, and the edges were approximated by the interrupted iron-wire sutures. A large compress of lint was applied, and retained by the figure of 8 bandage. The patient was lifted into bed, and her thigh flexed upon a pillow. She soon recovered from the chloroform. A grain of opium was placed on her tongue, and ordered to be repeated every second hour. She was directed to take ice and chicken broth, and to have a linseed poultice applied to the abdomen.

11 o'clock P.M.—I visited the patient, and found that she slept well since the operation, and there was no return of the vomiting, but she complained of a flatulent pain in the abdomen. Tongue clean and moist. Pulse 80 in the minute, soft and regular. Shortly after I entered the bedroom she became pale, and vomited a small quantity of sour-smelling fluid. Ordered iced milk with lime water as drink, and small quantities of brandy in iced water. Poultice to be renewed, and a dry turpentine fomentation to be applied to the abdomen. The grain of opium to be continued every second hour.

July 12th.—10 o'clock A.M.—Countenance natural. Pulse 72 in the minute. Patient was restless during the early part of the night, and complained of a colicky pain in the abdomen, which was relieved by a repetition of the turpentine fomentation. She slept well afterwards until seven o'clock A.M., when she vomited several times, sour-smelling fluid. She passed water during the night. A sinapism was applied over the epigastrium, and teaspoonfuls of brandy with ice were frequently given. The following mixture was prescribed :—

℞ Acid hydrocyanic, dil., ♏viij.
Bi-carb. potassæ, ʒij.
Tinct. opii., ʒi.
— Card. co., ʒij.
Aquæ ad., ℥viij. M.

Sumat cochl : duo amplacum uno succi limon : in effervescent : tertiis horis.

11 o'clock P.M.—Pulse 80. Countenance natural. Abdomen not tender. Patient vomited four times since morning. Took brandy, ice, chicken broth, and effervescing mixture; also the opium.

13th.—Patient vomited four times during the night.

Dressings removed. Wound looks very healthy; pulse 72.

10 P.M.—Stomach has not been sick since morning; no pain or uneasiness complained of. Continue treatment.

14th.—Pulse 72; stomach quite settled; two-thirds of the central portion of the wound have united by "the first intention;" slight red blush around the wound; lower suture removed; slight discharge from lower angle, of a sanguineous fluid; linseed poultice applied.

9 P.M.—Warm water dressing.

15th.—Pulse 80; tongue covered with a white fur; patient passed a restless night; had pain in region of umbilicus; discharge from wound fœtid, thin, and bloody; "Condy's fluid" applied with warm water dressing; ordered,

Calomel, gr. vj.
Pulv. opii. gr. iij.

in pulv. xij. equal; i. tertiis horis sumend.

Turpentine fomentation to abdomen, and linseed poultice.

11 P.M.—Pulse 80; abdomen full, but not tender on pressure.

16th.—Discharge from wound copious and bloody; carbolic acid lotion applied; omit powders.

17th.—Discharge from wound *feculent*, and very copious.

18th.—Patient looks well; discharge from wound like half-boiled egg; it comes out with a sudden gush, and scalds the wound and surrounding integument, which is reddened.

28th.—The fecal fistula has closed naturally, the discharge lessened each day; the bowels were acted upon by enemata, administered with O'Beirne's tube.

August 8.—The fecal fistula opened again, and discharged for a few days; a bright papilla (with small orifice in its centre) appeared in the funnel-shaped orifice at the lower angle of the wound; an occasional touch of solid nitrate of silver assisted nature in closing the fistula, and the patient is now in the enjoyment of excellent health, and has no tendency to protrusion of bowel, the operation having performed a radical cure.

Observations.—On reviewing the progress, treatment, and termination of the foregoing interesting case, the following practical facts may be summarized, viz.:—

The shape of the hernia (which was femoral) resembled the oblique inguinal form, in consequence of the direction which the tumour assumed by passing over Poupart's ligament, and extending in the direction of the anterior superior spine of the ilium; on close examination, however, the diagnosis was not difficult, as the neck of the tumour was traceable beneath Poupart's ligament, in the direction of the femoral ring.

Before deciding upon operation, I tried the effect of purgative injections, administered by means of O'Beirne's long tube (passed fully up into the bowel), and the internal use of opium. Notwithstanding the bowels having acted freely, and vomiting having ceased, the hernia remained unaltered; the taxis was not tried in consequence of the tenderness and unusual tension of the hernia, and the result of the case showed the propriety of this practice. The sac was opened in consequence of the dark appearance of the intestine, as seen through it.

The stricture was very tight and was caused, as usual, by the upper margin of the saphenic opening (Hey's ligament), and required much care to divide it without injury to the gut, which was tense and very darkly congested. The patient was kept under the influence of opium for many days, to allay the peristaltic action of the bowel. An intestinal or fecal fistula formed on the 7th day; the neck of the sac and the adjoining peritoneum became adherent, and prevented extravasation of the contents of the intestine into the cavity of the abdomen, and in due time, these newly adhered parts became cicatrized, and a natural cure of the fistula was effected.

The case proves, in my judgment, the importance of *early operation* and avoidance of the mischievous taxis; had the former been delayed (though the constitutional symptoms did not appear to be urgent), and the latter resorted to, death from gangrene of the intestine must, I believe, have been the result.

REMARKS ON FEVER AND INFLAMMATION.

By B. KELLY, M.D., L.K.Q.C.P.I.

THE aphorism, "Ubi irritatio ibi fluxus," is scarcely more applicable to the blood than to the nervous fluid. Nor is it alone in morbid conditions of the system we see the force of this truth exemplified. In concentration of thought, as in deep meditation and study, the senses are so far blunted and kept in abeyance that powerful external impressions often fail to arouse them. The state of mind produced by moral emotions also sufficiently prove the influence exercised upon the nervous system, and, through it, on the circulation by subjective impressions alone. Thus, chagrin and jealousy induce jactitation and feverish excitement; pleasure and hilarity, on the contrary, are attended by an equable temperature.

It is thus, doubtless, that in phthisis, pneumonia, pleuritis, &c., during their inflammatory stage or acme, so great is the accumulation of nervous energy in the diseased organs that, all other portions of the body being in a great measure deprived of it, a condition analogous to section or paralysis of the organic nervous system ensues; and hence the sympathetic fever which always accompanies the diseases in question. Why the vasomotor system should suffer more than the cerebro-spinal by this abstraction and local congestion of the nervous fluid may possibly be owing to the fact that the former presides more especially over the functions of circulation and nutrition, and is thereby more generally and intimately diffused throughout the economy. The exacerbations and remissions which occur in the course of acute disease, and which correspond to the ebb and flow of the nervous fluid, may thus serve as a faithful guide to indicate the amount of irritation centred in the inflamed part.

Although the organic nervous system is not directly under the voluntary control of the cerebro-spinal, it by no means follows that its nervous power does not emanate from it. Impressions made upon the peripheral portions of the sympathetic, whether located in the intestines or in other abdominal or thoracic viscera, must necessarily traverse the corresponding ganglia in order to be felt by the nervous centres. In like manner the excitations—the result of these impressions—produced in the central organs, and carried by the efferent branches, slowly repeat the same circuitous process ere they can reach the muscles and other tissues to which these nerves are distributed. We thus can easily account for the tardy manner in which non-striped muscular fibre contracts under the influence of a stimulus; but its energy is not the less powerful or persistent for its slowness.

All acute inflammations and most fevers are ushered in or preceded by a chill, which usually lasts for a period commensurate with the severity of the disease of which it is the harbinger. In a simple phlegmasia it is generally single, but in fever it is invariably multiple, and consists of a quick succession or series of horripilations. This rigor, as it is called, is characterised by a shrivelled state of the skin, by contraction of the capillaries, and, as a consequence, by a notable decrease of temperature. The first action of the morbific cause, whatever it may be, whether fibrile or inflammatory, seems to expend itself upon the organic nervous system, and to stimulate it to its utmost capacity. We know that excitation of the sympathetic is followed by contraction of the arterial capillaries, slowness of the circulation, and diminution of the animal heat of the body. These phenomena tally in a remarkable manner with the premonitory symptoms of febrile and inflammatory diseases. Following the chill there next appear suffused redness of the whole surface, turgidity of the vessels, and elevation of temperature. The same, it is unnecessary to say, is observed in section or paralysis of the great sympathetic. But how are we to account for such a striking similarity of effects in conditions so apparently opposite? The old-school pathologists explained away the phenomena of the first stage of inflammation in a very off-hand and, to themselves, a very satisfactory manner.

The capillaries, said they, at first contract, because they possess the inherent power of contraction; and secondly, they dilate, because they possess the power of dilatation! This, certainly, was very accommodating of the capillaries. But why do the capillaries in inflammation at first contract, and soon afterwards dilate? These vessels, being under the control of the sympathetic, remain contracted so long as sufficient nervous fluid is conveyed to them; but, as the result of over-stimulation of any portion of the nervous system is exhaustion, or paresis, the vessels soon dilate from sheer pressure of the blood, and not from any dynamic activity inherent in themselves. In a word, the stage of contraction coincides with nervous irritation, and that of dilatation with exhaustion of nervous energy; and as all muscular fibre, whether organic or striated, is incapable of contraction independently of nervous fluid, or some agent analogous to it, so does its extension depend upon mechanical force. And as a state of contraction of the capillaries is attended by depletion of the tissues, so does the opposite condition, or that of dilatation, induce hyperæmia, stasis, and congestion.

In a simple phlegmasia, the irritation which disturbs the nervous system, and, through the latter, the circulation, is peripheric, and is located in the organ or tissue inflamed. In fever, on the contrary, the irritation is central, and depends upon a general specific intoxication of the system; and hence the treatment best adapted to the former will prove utterly worthless, or even destructive, to the latter, and *vice versa*. It may, however, be here objected that if the irritation which gives rise to a phlegmasiæ be peripheric, and confined solely to the part inflamed, how comes it to pass that the temperature of the whole body is exalted as in common continued fever. That the heat of the inflamed tissue is greatly increased, there can be no doubt, as is easily witnessed in anthrax or furuncle; but this increase is only relative as regards the entire system. Owing, as already remarked, to the abstraction of the nervous fluid, and its concentration within a narrow focus, a condition of the sympathetic ensues somewhat similar to what follows its section or paralysis. The heat, moreover, in inflammation, is more subjective and imaginary than positive or objective. In continued fever the contrary of this obtains. The patient invariably complains of coldness; whereas, if the hand of the physician, or a thermometer, be applied to any part of his body, a notable elevation of temperature will be found to exist. The state of the circulation is also diametrically different in both cases. In inflammation the pulse is generally increased in frequency and force, the local and partial paralysis of the great sympathetic being more than counterbalanced by a morbid erethism of the cerebro-spinal system. The arteries throughout the body, and more especially those leading to the point inflamed, pulsate vehemently, as though some great obstacle, the removal of which they had undertaken to accomplish, had lain direct in their course. In fever, on the other hand, the circulation is *apparently* quickened, but diminished in force; the pulse, consequently, is rapid and fluttering, but weak and compressible; hence the great tendency to passive hæmorrhages and hypostatic congestions shown by the disease. The blood also retains more or less of its arterial character after having traversed the tissues of the body, proving conclusively that nutrition, normal and physiological, is not only impaired, but in a great measure suspended; the fibrine is diminished, and a state of the muscular system resembling at first fatty degeneration, and finally atrophy, ensues.

The decrease of fibrine may be owing to some yet unknown change (probably of a catalytic type) in the albumen, as a highly fermentible substance, by the zymotic poison, or the fibrine itself may be primarily attacked by the same subtle and septic agent.

We agree with Lyons, that the increased circulation in fever is more apparent than real. This authority states:—"Indeed so imperfect are these contractions (ventricular) sometimes found to be, that the mass of the blood, instead of moving with increased velocity, is retarded, and flows more slowly than usual."

In inflammation the blood, especially the veinous, is surcharged with fibrine and carbonic acid; and although the muscles are wasted when the disease has continued a considerable time, nothing approaching fatty or waxy metamorphosis of their fibres is ever noticed.

Another remarkable difference between fever and inflammation is shown by the manner in which congestions, as they occur in both, usually comport themselves. In fever a pneumonia, for instance, will persist nearly during the whole course of the disease without effecting any change of a fatal or destructive nature in the lung tissue—neither purulent nor plastic infiltration taking place—the parenchyma of the organs becoming only somewhat more friable than normal, owing to lesions of a necrobiotic order induced in all the solids and liquids of the body. Pus formation is as much a natural and common consequence of an acute, unchecked, phlegmasia, as the absence of suppuration is characteristic of simple idiopathic fever. The ulceration of Peyer's patches, which sometimes ensues in the course of typhoid, forms no exception to the truth of this proposition. These bodies, like all other conglobate glands, become hypertrophied in fever; the nucleated vesicles in the interior of their stroma undergo cheesy or fatty degeneration, as the result of modified and impaired nutrition, and finally softening and sphacelus supervene. Their superficial location on the surface of the small intestine, where they are continually exposed to friction from the passage of fæcal matter, is highly favourable to their disintegration, and accounts, at the same time, for the comparative immunity enjoyed by the mesenteric and other ductless glands of the system. The ulceration of the larynx, pharynx, and œsophagus; the bed sores on the hips, nates, and other parts exposed to pressure or friction, afford additional proof of the fatal facility with which inflammation and sloughing arise from slight causes of irritation in the course of continued fever.

The eliminating function bestowed upon Peyer's patches in typhoid by many pathologists, is as erroneous as the one generally attributed to the kidneys in scarlatina, or to the stomach and bowels in cholera. The only stage at which expulsion of the putrid poison can well be said to take place is, when the glands are simply enlarged, and before ulceration has set in; but we have no presumptive evidence, much less positive proof, that such is the case. Nature, we are sure, never blindly destroys an organ which she had previously intended should subserve the office of an emunctory. And as the term "elimination" necessarily implies a physiological act, it would be repugnant in the highest degree to connect it with a morbid process like that of ulceration. The changes wrought in the economy, and especially in the glandular system, by the zymotic element of fever, are as material and fundamental in themselves as the lesions induced by corrosive and irritant poisons. It expends its virulence, so to speak, in operating these changes, much in the same way as the chemical quality of an acid is lost in neutralizing an alkaline base. There is, consequently, great wasting of the tissues—the poison being thus thrown off, not, indeed, such as it entered the system, pure and active, but modified and combined with effete organic matter. "Muscle, gland tissue, bone itself," as remarked by Lyons, "undergo manifest diminution in volume and density in the course of febrile diseases, often to an excessive degree." In this way, also, we can account for the remarkable fact of fever scarcely ever attacking the same individual a second time—all the organic liquids and solids of the body having undergone such profound modification from the poison while permeating the system, that even, when restored to health, they still retain the impress of its morbific action to so great an extent as to become impervious to all subsequent contagion of a similar kind.

Great stress is often laid upon deafness when it arises as a symptom in typhoid; and physicians, not unfrequently, endeavour to draw an unfavourable prognosis from its presence. But the reason, we think, why deafness is thus invested with greater importance than any other physical or rational sign of the disease, is due to the fact that we commune more generally with patients through their hearing than any, or all, of their other senses.

Indeed, so far as we have observed, the sight, smell, taste, and even touch of fever patients are as often impaired and blunted, as is the auditive faculty. Occasionally there is undue sensitiveness of the acoustic and optic nerves, but such an accident is comparatively rare, and, when it exists, should make us rather suspect the presence of a disease simulating typhoid. The sordes on the teeth, lips, and gums; the thick, clammy film, often veiling the cornea and conjunctiva; the desquamated, dust-like particles obstructing the nares and covering the alæ nasi, without exciting any sense of discomfort, prove conclusively the degree of intellectual hebetude and nervous torpor in which the individual is plunged. These accidents are in themselves as significant as the temporary and partial loss of hearing, but they fail to impress us as vividly as the latter for the reason already adduced.

An unfavourable prognosis may be safely drawn from contraction of the pupils, especially when well-marked and persistent. This symptom constitutes, *per se*, the strongest evidence of the complete paralysis of the organic nervous system by the typhic poison. The general hyperæsthesia of the surface of the body, so common in continued fever, would also seem to indicate that the erethism of the sensory nerves is in a great measure vicarious of the nervous energy withheld from the sympathetic. The pulse in these cases is remarkably quick, small, and fluttering, which clearly indicates the employment of neurosthenic agents, and which nearly always ushers in a fatal termination.

A correct prognosis, whether favourable, or otherwise, can also be often determined from the condition of the tongue, and intellect of the patient. When the former remains moist and comparatively clean throughout the course of the disease; when the reason is unimpaired, or only subject to slight paroxysms of stupor and delirium; and when, withal, there is a keen appetite for the more substantial kinds of food—approaching a true boulimia, the case becomes one of extreme gravity, and will require all the vigilance and skill of the physician to prevent a fatal issue. The most deceptive, and, at the same time, the most formidable cases of typhoid fever that have ever fallen under our observation, were those in which the tongue was moist and uncoated, the mental faculties unclouded, or slightly impaired, and the appetite ravenous.

ON THE PATHOLOGY AND SIGNIFICANCE OF CERTAIN ENDO-CARDIAL MURMURS.

By THOMAS HAYDEN, M.D., F.R.C.S.I., F.K.Q.C.P.I.

[Abstract of Paper read before Section A (Medicine) of the British Association at Oxford, August 7, 1868.]

Dr. Hayden commenced by classifying murmurs originating within the heart under two heads—namely, those occurring simultaneously with the sounds, and usually designated "systolic" and "diastolic" respectively; and those which occur during the intervals of silence or so-called periods of repose between the sounds. These periods of silence are two in number, and distinguished as the short or "systolic" pause, occurring between the first and second sound; and the long or "diastolic" pause between the second and succeeding first sound. The designations, "systolic" and "diastolic," he has applied to these periods by preference, because they imply the corresponding state of the ventricles in regard to contraction and relaxation, and thereby assist the mind of the student in interpreting contemporaneous murmurs.

Systolic murmurs are of two kinds—viz., those which accompany, and those which supersede the first sound.

Diastolic murmurs were similarly classified.

The relative significance of these two kinds of murmur, in association with the first and second sound of the heart respectively, was next pointed out, as was likewise the condition of the valves to be met with in each case.

Murmurs occurring within the time of the short pause are theoretically of two kinds—viz., "post-systolic," which immediately follow, and are in direct continuity with, the first sound, extending to a variable length, into the short pause, but in most instances falling short of the second sound. Such murmurs, he showed, were confined to the apex of the heart, of mitral origin, and due to simple valvular incompetence, without organic valvular disease.

The second kind of murmur falling within this period—viz., towards its close, and immediately preceding, and continuous with, the second sound, he designates "præ-diastolic." Practically, the latter kind of murmur is exocardial; he has not met with a single example of such a murmur due to an endo-cardial cause. A case was given, in which it was represented by a circumscribed pericarditic friction-sound, and another in which the murmur of an abdominal aneurism, synchronous with the pulsation of the abdominal aorta, and occasionally audible by transmission at the apex of the heart, corresponded in time with the period immediately preceding the second sound, and was, therefore, a veritable præ-diastolic murmur.

Murmurs developed within the period of the long or diastolic pause are of two kinds—namely, "post-diastolic," which are continuous with, and, as it were, appended to, the the second sound, but falling short of the first. These murmurs are basic, usually aortic in origin, and expressive of imperfect closure of the aortic valves, the consequence of incipient, and as yet very partial structural change confined to the edges of the valvular segments.

Finally, the murmurs which occupy the terminal portion of the long pause, he designates "præ-systolic" in preference to the title "auricular systolic" given to them by Dr. Gairdner.

These latter murmurs are by no means uncommon, are usually confined to the area of the apex, and pathognomonic of mitral constriction.

Numerous examples were given of the several species of murmur mentioned, with detailed history of cases, and the classification of murmurs, with their relationship to the several phenomena constituting the cycle of cardiac action, was illustrated by diagrams.

Hospital Reports.

DR. STEEVENS' HOSPITAL.

CASE OF LEUCOCYTHÆMIA.

UNDER THE CARE OF

H. FREKE, M.D., F.K.Q.C.P.I., M.R.I.A.,

PHYSICIAN TO STEEVENS' HOSPITAL.

(Reported by S. Flood, M.B., F.R.C.S.I., Clinical Clerk.)

J. M., aged 51, a constable in the Royal Irish Constabulary, was admitted into Steevens' Hospital, on the 15th of June last, complaining of palpitation, general debility, loss of appetite, and inability to perform his duties.

He states that he always enjoyed good health until January, 1867, when he began to suffer from dyspepsia and weakness, which have continued up to the present time.

His symptoms were dyspnœa; palpitation increased by exercise, or going up stairs; vertigo; dimness of vision; general debility; anorexia constipation; pyrosis; occasional lancinating pain in the region of the spleen and left shoulder; emaciation. The mucous membrane of the conjunctivæ and mouth was pale and almost bloodless. Legs œdematous; skin sallow and dry; tongue clean and pointed; abdomen tumid; appetite very capricious; bowels constipated. No pain on pressure over any portion of the abdomen; liver enlarged one finger's-breadth below the false ribs. Respirations 18, lungs apparently healthy; pulse 96, weak; temperature 99°. Area of precordial dulness slightly increased; heart's sounds heard more distinctly than normal, and over an increased space; no bruit. Urine acid, sp. gr. 1030, depositing a copious brick-dust sediment of lithates; no sugar; spleen not perceptibly enlarged; thyroid body of natural size; great depression of spirits. Cervical, axillary, inguinal and iliac glands enlarged (many of them to the size of a chesnut), and distinctly indurated. A loud and harsh bruit is heard on placing the stethoscope over the enlarged glands at the root of the neck on the left side. Never had hæmorrhage of any sort. The patient attributes his illness to exposure to cold and wet.

In the absence of any history of hæmorrhage, malarious or malignant disease, it was difficult to arrive at an exact diagnosis, until that form of leucocythæmia, described by Dr. Hughes Bennett and Virchow as affecting the glandular system without splenic enlargement, suggested itself.

A microscopic examination of the blood on several occasions verified this opinion. The number of red and white corpuscles in the field of the microscope was about equal. Several of the red globules appeared irregular in shape.

The treatment consisted in the administration of various salts of iron in full doses; strychnia, quinine, iodine, and liberal diet; and all without the slightest beneficial effect; the patient presenting the same strikingly anæmic look which was so conspicuous on his admission.

He was discharged on the 1st of August, and again readmitted on the 3rd, suffering from severe diarrhœa, which has continued up to the present time quite unchecked by acetate of lead and opium (Graves' pills); katechu, kino, logwood, opium, chalk, sulphate of copper, and nitrate of silver, &c., &c.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief notes by Dr. Tonge.)

Pneumonia.—Arthur R., æt. 14, no occupation. Admitted April 1; discharged May 11. In hospital 40 days. *Recovery.* While sweating drank 2 pints of cold water; shivering soon afterwards. On 2nd day, pain in left side; cough and feverishness. On admission face flushed; drowsiness; tongue coated; pulse 120; respiration 36; left lung slightly dull in front, completely dull below spine of scapula behind; fine crepitation and bronchial breathing over dull space; sibilus elsewhere; 6 days later less bronchial breathing and bronchophony; scanty white frothy expectoration; 12 days later lower one-third of left lung dull; distant vesicular breathing; crepitation at right base; rhonchus and sibilus at upper part of lungs; 6 days later breathing everywhere vesicular; lower one-third of left lung still slightly dull.

Liquor ammon. acetatis, aromatic spts. of ammonia, and spt. eth. nitrici (17 days). Then bark, muriatic acid and squills. Brandy to 9 oz. Turpentine stupes.

Tubercular Pneumonia.—J. M'D., æt. 23, potman. Admitted April 14. *Died* on April 22. In hospital 8 days. Three brothers died of phthisis. Profuse hæmoptysis 18 months ago; slight cough previously. Out of work, and "worried" of late; has lost flesh much; very weak and feverish 1 week. On admission emaciated; tremulous; delirious; dulness diminished; expansion and cracked pot sound under right clavicle; gurgling crepitation; tubular breathing and pectoriloquy below; dulness and coarse crepitation over whole back of right lung; breathing bronchial over lower third; purulent expectoration streaked with blood; tongue red and glazed; pulse 130; respiration 60. Gradually became weaker and died on 22nd.

Post-mortem.—Old adhesions of and recent lymph on right lung; right lung and apex of left studded with miliary tubercles, and completely hepatized by pneumonia; cavity in each apex; ulceration of back of true vocal cords; ulcers in ileum.

Liquor ammon. acetatis, aromatic spts. of ammonia, chloric ether, and squills; quinine and opium. Brandy 12 oz. Turpentine stupes.

Chronic Peritonitis—Disease of Ovaries and Bladder.—A. C., æt. 19, housemaid. Admitted December 26; *died* on May 7. In hospital 72 days. Amenorrhœa 9 months. Pain, tenderness, and swelling in hypogastric and left inguinal regions; vomiting, loss of flesh and strength, and occasional severe headache, 6 months; jaundice 4 months ago, and again 1 week ago; diarrhœa 3 months. On admission skin dark and sallow. Tender tumour just above pubes; dull on percussion; as large as two fists. Appetite pretty good; often capricious. Tongue clean. Much diarrhœa throughout. Occasional vomiting. Progressive emaciation and weakness. Death on March 7.

Post-mortem.—A few tubercles at apices of lungs; liver fatty. The tumour was formed of some coils of small intestine matted together by lymph. Old abscess between uterus and bladder. Superficial ulceration of os uteri. Cyst of each ovary. Black fungoid excrescences on posterior wall of bladder. Intestinal mucous membrane healthy.

Bark and hydrochloric acid. Glycerine and syrup of iodide of iron. Chloric ether and sp. ammon. arom. Astringents for diarrhœa. Wine 4 oz.

Ulcer of Stomach—Hæmatemesis.—J. G., æt. 38, labourer. Admitted November 4; discharged November 19. In hospital 15 days. *Recovery.* Had cholera 11 years ago. Pain at epigastrium, 2 months; increased by food, which is vomited soon after it is taken. Sour risings. Profuse hæmatemesis on day of admission. Motions dark and loose since. Epigastrium tender. No dorsal pain. Is very anæmic.

Tannic acid (1 day). Then sulphate of magnesia and dilute sulphuric acid.

Ulcer of Stomach—Hæmatemesis.—J. G., æt. 21, barmaid. Admitted May 18; discharged July 1. In hospital 44 days. *Very much relieved.* Pain in chest and between shoulders 2 years. Vomited a clot of dark blood three weeks ago. Slight hæmatemesis twice or thrice daily since. Bowels confined. Appetite bad. Nausea after food. Tongue brown. Pain at epigastrium on 2nd day after admission (23 days). Vomited about half an ounce of blood o.m. Discharged because unwilling to follow treatment.

Hydrocyanic acid and bicarbonate of soda (25 days). Then quinine and iron. Hydrochloric acid lotion.

Ulcer of Stomach (?)—Caroline D., æt. 32, married. Admitted April 21; discharged May 7. In hospital 16 days. *Recovery.* Typhus 16 years ago; confined 16 months ago; dyspeptic since. Suckled child for 12 months. Weakness, flatulence, epigastric pain, worse after food, sour risings, evening vomiting, occasional diarrhœa, motions dark, appetite bad, pulse feeble.

Aromatic spts. of ammonia, and mixt. camph. (7 days). Sulphate of iron and quinine.

Vomiting.—John R., æt. 41, street fruit-seller. Admitted July 8; discharged July 13. In hospital 5 days. *Recovery.* Vomiting and epigastric pain 1 month; pain over whole abdomen, 4 days; sour risings; constipation; tongue coated; pulse 76; constant vomiting of dark green fluid.

Hydrocyanic acid, chloric ether, and bicarbonate of soda.

Dyspepsia.—A. F., æt. 28, housemaid. Admitted November 3; discharged November 23. In hospital 20 days. *Recovery.* Family phthisical; catamenia irregular 3½ years; loss of flesh; vomiting and epigastric pain 6 months; four attacks of hæmoptysis in last 4 months, the last 14 days ago; cough 2 months; much tenderness of abdomen;

slight dulness, harsh bronchis, and increased vocal resonance at left apex; no vomiting after admission.

Pepsine, bismuth and hydrocyanic acid, bicarbonate of potass. Aperients.

Dyspepsia.—Clara C., æt. 35, perfumer's assistant. Admitted September 29; discharged October 27. In hospital 28 days. *Recovery.* Catamenia absent 7 months; and waterbrash 7 months; pain at epigastrium, at first slight and occasional; appetite bad; epigastrium tender; constant vomiting; pulse feeble.

Hydrocyanic acid and bicarbonate of soda, pepsine, and dilute hydrochloric acid, sesquichloride of iron and quassia.

COUNTY LIMERICK INFIRMARY.

CIRCUMSCRIBED FEMORO POPLITEAL ANEURISM OF LEFT LEG: FAILURE OF PRESSURE: LIGATURE OF FEMORAL ARTERY IN PORTER'S SPACE: SECONDARY HÆMORRHAGE ON 15TH DAY: LIGATURE OF EXTERNAL ILIAC ARTERY: DEATH FROM PYÆMIA AND GANGRENE OF FOOT AND LEG.

Under the care of Dr. THOMAS J. GELSTON.

James O'Dea, æt. 46, seen by me as a dispensary patient on 27th June, 1868, when I at once had him removed to the County Infirmary, where I saw him in consultation with Dr. Wilkinson at three o'clock P.M. Is a sawyer by trade. He received no injury; had venereal; drinks freely, and suffers from rheumatism. The enlargement begins at the angle of Scarpa's space, and extends to the lower margin of the popliteal space. The sound limb measures above the knee 12½ inches, whereas the diseased one at the same point 15½ inches. Visible pulsation; great œdema of leg and foot. He has been blistering and poulticing the tumour on his own responsibility. No medical man saw him. Heart sounds healthy. Patient very irritable and nervous. Commenced compression at once, and applied ice to the tumour. All pulsation ceases on pressure being applied to the femoral above the tumour; but the sac cannot be entirely emptied. Says he never remarked anything wrong till about a month since. Glands in groin enlarged, and distinct fremisseunent along entire course of artery of diseased limb, and slightly so in sound one.

July 1st.—Compression kept up since the 27th of June. The aneurism measures this morning 17½ inches. He now cannot bear any pressure in the groin, and the clamp which was applied in the thigh has produced a slough; great œdema of entire limb up to groin; so we decided on tying the femoral artery, which I did on the morning of July 2nd, by Porter's operation, by a transverse incision half-an-inch below Poupart's ligament; the vessel was easily secured, and pulsation immediately ceased. Applied a flannel bandage up to one knee, and hot jar to foot. To have his meat; no porter or ale. Scarcely a drop of blood was lost during the operation. Six P.M.—Going on very well; had some pain in his knee during the day, which is now quite gone. Temperature of foot and leg good; no pulsation in tumour. To have 40 drops tinct. opii at bedtime. From this time he went on well. Tumour daily getting more solid, and measured on the 10th July 15½ inches, when on July 17th, at 11 A.M., secondary hæmorrhage took place, pressure was applied in groin, and when my father and I arrived, I at once cut down and tied the external iliac artery by the usual operation. Scarcely a drop of blood was lost, and the hæmorrhage was completely arrested. To have 40 drops tinct. opii at once.

All went on well till the 19th July, when fresh bleeding took place from the old wound from the distal end of the femoral; when I arrived all had ceased, so I applied a graduated compress. Patient very weak. Circulation feeble, but temperature of leg and foot good. Went on very well till July 21st, when the bleeding again took place. We enlarged wound, but could not get at any vessel; all the parts sloughy, plugged wound with sponge and a saturated solution of perichloride of iron in glycerine, and to keep up pressure over all with the hands, which was done by all the patients in the hospital by turns, night and day (till his death).

24th.—Bled again; plugged wound as before.

28th.—Bled again, tried in vain to secure some vessel, but failed. All parts sloughy, and full of pus; would not hold a tenaculum or needle.

30th.—No bleeding since, but gangrene is setting-in in the foot. To be kept warm.

31st.—Gangrene spreading; no return of hæmorrhage; patient very weak, and sinking rapidly. Died at two P.M. of the morning of August 1st, 1868.

Ten hours after death the femoral artery was found extensively diseased, and the hæmorrhage took place from the distal end of the femoral; all parts sloughy and full of pus. The ligature on the external iliac came away when touched, but the artery was impervious. We did not open the sack, which was quite soft, not wishing to disfigure the remains too much.

The failure of the ligature on the common femoral in this case I attribute to the diseased condition of the vessel.

◆

Summary of Science.

(*Specially edited and Compiled for the Medical Press and Circular.*)

By C. R. C. TICHBORNE, F.C.S., F.R.G.S.I., Etc.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

OCCLUSION OF HYDROGEN-GAS BY METALS.

The master of the mint has applied this term to the absorption of gases by what he terms colloid metals.

A new method of charging the metals with hydrogen at low temperatures has lately been discovered by him.

When a plate of zinc is placed in diluted sulphuric acid hydrogen-gas is freely evolved from the surface of the metal; but no hydrogen is occluded and retained. A negative result was, indeed, to be expected from the crystalline structure of zinc. But a thin plate of palladium in the same acid, and brought into contact with the zinc, soon becomes largely charged with the hydrogen, which is transferred to its surface. The charge taken up in an hour by a palladium plate amounted to 173 times its volume.

Although the hydrogen enters the palladium, and no doubt pervades the whole mass of the metal, it exhibits no disposition to leave that substance even in a vacuum at the temperature of its absorption. Occluded hydrogen is therefore no longer a gas, whatever may be thought of its physical condition. When palladium charged with hydrogen is left exposed to the atmosphere, the metal is apt to become suddenly hot, and to lose its gas entirely by spontaneous oxidation.

The condition of hydrogen, as occluded by a colloid metal, may be studied with most advantage in its union with palladium, where the proportion of gas held is considerable. The largest absorption of hydrogen observed was in the case of palladium thrown down upon a thin platinum wire by electric deposition. Such a specimen of metal occluded 982 times its volume of hydrogen, or by weight—

Palladium, 99·277
·723

100·

or an approximation to the compound Pd H.

Professor Graham thinks that the passage of hydrogen through metals is always preceded by the condensation, or occlusion of the gas. The "solution affinity" of metals appears to be nearly confined to hydrogen and carbonic oxide; metals are not sensibly penetrated by other gases than these.

THE COMPOSITION OF COMETS.

Mr. W. Huggins describes the appearance of the comet seen in the telescope on June 22nd. He found the light of this comet when examined with a spectroscope furnished with two prisms, to be resolved into three broad, bright bands. The author gives a measure of these bands, and a diagram of their appearances. This spectrum of the comet agrees exactly with a form of the *spectrum of carbon*, which he observed and measured in 1864—viz., the spectrum of the induction spark taken in a current of olefiant gas. The remarkable close resemblance of the spectrum of the comet with that of carbon necessarily suggests the identity of the substances by which the light is emitted in both cases. Phosphorescent substances give discontinuous spectra, but we cannot consider cometary light to be of a phosphorescent character.

ADULTERATION OF SUBNITRATE OF BISMUTH.

Dr. Redwood has met with two samples of adulterated subnitrate. The new sophistication seems to be phosphate of lime. M. Roussin had previously found a sample containing 28 per cent. of phosphate of lime; and we are glad to find, for the credit of the British manufacturers, that the two samples examined by Dr. Redwood were of foreign make.

This fraud is detected in the following manner:—Equal quantities of the subnitrate and tartaric acid are dissolved in water, acidulated with nitric acid. To this is added a strong solution of carbonate in excess. The subnitrate of bismuth will remain clear, even after boiling; if it contains one or two per cent. of phosphate of lime a white precipitate will fall on boiling.

ON PHOSPHORIZED OIL.

M. C. Méhu writes upon the above subject in the *Journal de Pharmacie et de Chime.* The oil is used in paralysis and other diseases. M. Méhu says that the preparation of the French codex *(Huile Phosphorée)* is a bad preparation; both uncertain in its composition and changeable.

One of the causes of this instability is the impurities in the almond oil. He therefore heats the oil in a porcelain capsule during one-fourth of an hour to a temperature of 150°, and finally to a temperature of 200 to 250° for six minutes.

It gives off the vapour of water and certain organic substances easily alterable; at the same time the oil becomes completely blanched. It is only necessary to filter it.

One centigramme of phosphorus is then placed in a flask, and a gramme of oil, prepared as above, is added.

The phosphorus must be quite transparent, and free from red or opaque phosphorus. The flask is placed upon a salt-water bath, and the mouth opened once or twice, to allow the heated air to escape, and finally the temperature is raised to 80 or 90° C. without shaking; the flask is then closed and shaken violently, until all the phosphorus is dissolved. The phosphorus is not deposited again on cooling.

The oil at 1-100 is phosphorescent when the flask is open; the space filled with air exhibits a magnificent phosphorescent cloud, and the vapour of phosphorous acid is formed.

An oil which does not contain more than two grammes of phosphorus for 1000 does not shine in the dark, and the vessel is no longer filled with white clouds of phosphorous acid.

Such an oil is preferable for daily use to one which is undergoing a partial alteration each time it is opened.

The phosphorescence of any oil is a sign of its alteration in the air. If, however, a few drops of æther are added to the oil, the faculty of shining in the dark is instantly stopped. Sulphide of carbon and turpentine possess this property, but essences of thyme, rosemary, and mint, and alcohol do not possess it. The vapour of æther alone is quite sufficient to stop the phosphorescence.

DETECTION OF NITRO-GLYCERINE.

A. Weber gives us the following method for detecting nitroglycerine in case of poisoning. The organic material or substance is comminuted and then extracted with ether or chloroform. The tincture is mixed with two or three drops of pure aniline and evaporated on a water-bath.

To the residue a few drops of concentrateds ulphuric-aci re then added, when, if nitro-glycerine is present, a purpled colouration appears, which changes to a dark green on dilution with water. As little as ·001 grain of nitro-glycerine may thus be identified.—*Foreign Correspondent of the Chemical News.*

SPECTRA OF POTASSIUM AND BARIUM.

Mr. J. Freeman *(Chemical News)* recommends the use of a mixture of the chlorates instead of the nitrates for viewing the spectra of their metals, and there is no doubt that his remarks are applicable to other metals. The increased temperature produced from the combustion of a chlorate with charcoal, compared to a nitrate, renders visible, in the case of potash, all the lines with the exception of one, in the blue, many of which are invisible when only viewed from the combustion of nitre. The same remarks apply to barium.

PERSULPHIDE OF HYDROGEN A TEST FOR STRYCHNINE.

Under the heading of "A Contribution to the Knowledge of Persulphide of Hydrogen," Dr. Hofmann has forwarded to the Royal Society an account of a most curious reaction, which promises to be of considerable practical value. The composition and even the existence of persulphide of hydrogen has remained so far an open question, although examined by Schule, Berthollet, and Thenard. It remained for Dr. Hofmann, with his usual facility, to decide this point, and to give the account of some experiments which promise to have a practical bearing. On adding a cold saturated solution of strychnine in strong alcohol to an alcoholic solution of polysulphide of ammonium, brilliant crystalline spangles soon begin to appear in the liquid, and after twelve hours the vessel is filled with beautiful orange-red needles, frequently attaining the length of a centimetre. After the removal of the mother liquor it is only necessary to wash these crystals once or twice with alcohol to render them quite pure. They are insoluble in water, alcohol, and ether, and also in bisulphide of carbon. The crystals are composed of one molecule of strychnine with one mol. of persulphide of hydrogen. This compound C^{21} H^{22} N^{2} O^{2}, H^{2} S^{3} goes far to prove the existence of a persulphide of hydrogen.

Quinia, cinchonine, brucine, and several other vegetable bases were respectively submitted to the action of an alcoholic solution of polysulphide of ammonium, but in no case was a similar phenomenon observed. It therefore becomes evident that not only does Dr. Hofmann's experiments bear a more than ordinary scientific interest, but that a mode of preparing strychnine and also a test for that important alkaloid is thus shown.

SILICI-IODOFORM AND IODIDE OF SILICUM.

Iodide of silicum is formed by passing iodine over red-hot silica, the iodine vapour must be passed with perfectly dry carbonic acid—as thus obtained it is in white cubic crystals. It decomposes water with the formation of silica, and hydriodic acid, with the liberation of hydrogen, and the precipitation of iodine. By causing hydriodic acid to act upon silicum in the presence of hydrogen, a liquid product was obtained by M. Friedel, which was found to have the composition $Si\ H\ I_3$. Its density is 3·360. It does not, however, seem to be a stable compound. When decomposed by water, it yields a white substance, which liberates hydrogen, which M. Friedel supposes to be siliciformic anhydride.

PURE CARBONATE OF LIME.

Dr. Græger's process (given in the July number of the American Journal of Pharmacy) may be found useful in the arts, as pure lime is not easily procured economically. Burned lime, recently *slacked*, is digested with a solution of nitrate of ammonia, leaving the lime somewhat in excess. The liquid contains nitrate of lime and ammonia, none of the impurities found in lime being dissolved. Carbonic acid gas passed through this solution precipitates pure carbonate of lime as a dense crystalline powder. It is admissable to add to the liquid a little carbonate of ammonia before filtering it. The filtrate is neutralized with nitric acid, and serves again for dissolving burned lime. The only expense, therefore, is in generating the carbonic acid,—*Journal de Chemie.*

DETECTION OF ERGOT IN FLOUR.

In same journal we have an account of a method of detecting ergot in flour, a matter of some importance in many countries. M. Berlandt's process is based upon the decomposition of propylamin into marsh gas and hydrocyanic acid ($C_6\ H_9 N = 2\ C_2\ H_4 + C_2\ N\ H$). One part of the flour, 1 of caustic potassæ, and 6 water, are introduced into a small flask, which is connected, first, with a chloride of calcium tube, and then with a combustion tube of 5 mm. diameter placed in a combustion furnace; this tube is connected with a Liebig's potash apparatus containing distilled water. The combustion tube is heated to redness, and then the flask is heated for half-an-hour, while the potash apparatus is kept in ice. This liquid is afterwards mixed with sulphide of ammonia, evaporated to dryness, and dissolved in a little water. A few drops of diluted sesquichloride of iron produce a blood-red colour, in consequence of the formation of sulphocyanide of iron.

COLOURLESS IODINE.

Under this name a solution containing iodine, carbolic acid, and glycerine, has been introduced to the American profession. It is made by mixing—

Compound tinct. of iodine, ♏xlv.
Carbolic acid cry., ♏vj. (fused).
Glycerine, ʒviii.
Water, ℥v.

The colour of the iodine gradually disappears, and the solution eventually becomes colourless; this change is completed at 60° Fahrn., in eight or ten days, but if exposed in a water bath to a temperature of 90° to 100°, the change will be effected in eight or ten hours. The change is due to the carbolic acid, not to the glycerine. The character of the change is the probable transformation of iodine into iodoform.—*American Journal of Pharmacy.*

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 2, 1868.

"DOCTORS," CIVIL AND MILITARY.

THE late Mr. GUTHRIE made the remark that there is hardly a great functionary, a member of Parliament, or a clerk in any of the public offices which may have directly or indirectly to do with doctoring, who does not consider himself by virtue of his station or office better qualified to judge of all matters in physic and surgery than any doctor in the empire. In civil life, the medical man finds his views and professional action often combated and embarrassed by venerable people of either sex, who would not dare to question the opinion of their lawyer on a point of law, or their clergyman on one of controversial theology; but who hesitate not to evolve, out of their inner consciousness, any number of theories to hurl against the experience and science of the doctor. The latter, if he be a discreet man, learns to accommodate himself to circumstances—knowing that while bread and butter are not to be quarrelled with on slight pretences, the tendency of nature is, in most instances, to effect a cure; and that in the few exceptions, or where the case is really complicated or severe, he is pretty sure to be left in the full enjoyment of all the responsibility connected therewith, but also of all the odium, should unhappily the laws of mortality prove, as they are sure to do some time or another, more potent than his art.

As an example of what occurs in the public services, let us take the Army. According to theory, *and the regulations,* the medical officers are responsible in regard to all matters that bear upon the health of the troops, and it is perfectly right that they should be so. But what is the case in practice? There is hardly an officer of or above *Field* rank who now-a-days does not consider himself quite as capable as any doctor to form an opinion upon any sanitary question that may arise,—a belief in which they are encouraged by the higher authorities, who make a point of constituting sanitary boards of military officers, with a surgeon merely to give his opinion upon any matter regarding which it may be required. Men, not of the medical profession, have, as a rule, a very imperfect idea of what are called sanitary requirements, beyond what can be effected by the scavenger. They, therefore, consider that any proposal which does not include the use of the broom is not in its nature worthy of attention, while to a suggestion that does include the employment of that very useful, if not particularly scientific instrument, they reply that their noses and eyes enable them to form as correct an opinion as any medical man could in the existing conditions. But let us suppose that the report or representation of an army medical officer with regard to a question, say of barrack or hospital construction, has, after being duly commented upon, been forwarded to its destination, the chances are that it there subsides; or, should any reply be vouchsafed to the proposals, it is only an intimation that they shall be considered, or, perchance, included in the estimates for improvements to be effected at some distant future date.

With this the Military Medical Officer will, if he has tact and discretion, be satisfied; only he knows, probably from past experience, that he had better take a note of the circumstance. Should, unfortunately, illness occur among the troops under his charge, or defects be discovered by any of the many Inspecting Officers who from time to time go their rounds, woe betide the unlucky Surgeon who is unable to show that he has already brought the subject to notice! Thus, he finds himself in this happy position, that if he does suggest necessary improvements, the chances are much against their being carried into effect; whereas, if this knowledge deters him from doing so, and any circumstance should arise to direct special attention to the existence of defects, his prospects, as regards advancement in his department, are floored from that moment. A pleasant position truly! And yet, how can circumstances be altered? The public cares little by what precise means desired ends are attained, but it does care that the army for which it is made to pay exorbitantly shall be maintained in the highest possible degree of health and efficiency. Let, therefore, medical officers have, in reality, as they now have only in name, the entire superintendence of all matters bearing upon the health of the soldier. Let the cobbler stick to his last; the military officer to matters military; the medical officer having control and responsibility in regard to those that come within his proper sphere.

Doubtless, there are times, as for example in active service, when military requirements supersede all other considerations; but under ordinary circumstances, both at home and abroad, there appears to exist no actual reason why the principal medical officer in the command should not, through his subordinate officers, be held as supreme in sanitary questions, as the commanding Royal Engineer is with reference to his branch of the service; he being in turn responsible to the Director-General, who, in order that he might exert his proper functions, should be directly in communication with the Secretary of State for War, towards whom his standing ought to be in all respects equal to that of an Under Secretary.

There exist certain questions of sanitation that concern the military in common with the civil portion of the community. They ought really to be considered by a Board or Committee, consisting of representatives of each; the views arrived at, in so far as they concern the troops, being submitted through the Army Medical Department. As matters at present are, that department, in regard to the larger questions affecting the health of the soldier, holds little, if at all, better position, than it did at the end of last century. It is time that this anomaly should cease.

LORD AMBERLEY'S VIEWS ON ABORTION.

As we anticipated, the report of the discussion on Mr. Lawrie's communication to the Dialectical Society "On the Happiness of the Community as Affected by Large Families," has excited very justifiable indignation against the doctrines to which some of the speakers gave expression. On that occasion Lord Amberley, son of the leader of the Radical party in the House of Peers, the pet lordling of the Reform League, and the Liberal candidate for the representation of South Devon in the new Parliament, occupied the chair, and the assembly was *graced* by the presence of several females, whose views on morality appear to be very advanced indeed.

The author quoted Scripture to show that all the ills the world ever suffered under were due to the over production of the human race. He wound up the disquisition with the opinion that emigration, colonization, or any of the existent means of getting rid of the surplus population are only inefficient make-shifts, and that the only *panacea* is the small family system prevailing in France. So far Mr. Lawrie's paper was innocuous, for even if his arguments were not unsupported by practical experience, there could still be no great objection to persons restricting the number of their children by enforced self-denial. So far from the author's premises being true, it would seem evident that the high and increasing rates of wages even in the most over-populous places, and the existence on the face of the globe of whole continents of barren and uninhabited soil, indicate that increased rather than diminished population is what the world requires to attain the highest degree of happiness and civilization. It is simple nonsense for an author who desires to legislate for the whole world, to argue from individual grievances; and the absurdity was capped by a subsequent speaker, who said that an agricultural labourer of his acquaintance had only 8s. a-week, and three children, "owing to the fact that the people are landless, and that large tracts of ground were taken up by the hunting grounds of the aristocracy."

It is not, however, to Mr. Lawrie's proposal of small families that we object, but to the means openly and unblushingly proposed to remedy the difficulty, and the utter disregard by the speakers of the principle of right and wrong which conscientious persons derive from the teachings of religion. Feeling the hopelessness of inculcating universal self-denial as a remedy for their alleged grievance of over-production, they at once discard it, the only natural or right means of controlling over-population, and they look around them for means, holy or unholy, by which the world may be permitted to give full licence to its sensuality without incurring the penalty (as the Dialectics would call it) which nature and a just Providence provides. Before considerations of what they call expediency all conscientious or scriptural restrictions vanish, and they do not hesitate when a moral difficulty arises in their path to elbow it aside at once to make room for a feasible, if not very righteous plan of their own. We believe we have not misrepresented the opinions of those who took part in the debate.

Mr. Levy said—As to the way in which the limitation of families should take place, he did not think, with many, that each family should only have two or three children. Delicate persons would be better without any children, and the robust and capable ought to have the privilege of engendering a larger number than the average.

Dr. Chapman accepted the law of Malthus as a scientific truth. The tendency to procreation helped us to keep down the inferior races, and thus, with the palliative of emigration, he thought that the "struggle for existence" was, on the whole, beneficial to mankind. Probably, as civilization advanced, the mere animal propensities would become more easily kept in abeyance, and poverty, arising from our over-population, would cease.

Lord Amberley said the subject brought forward by Mr. Lawrie was of first-rate importance. There was no doubt that prevention of over-population was by far the most satisfactory method of attacking the evil. How was this idea to be best spread among the poorer classes? He was glad to hear from Mr. Bradlaugh that the working classes were beginning to debate this vital point. Unfortunately the influence of the clergy in common with that of society, and the natural passions of mankind, were opposed to the prevention of over-population. He ventured to think that the propositions of Mr. McSweeny, that the evils of over-population could be remedied by taking the hunting-grounds of the nobility, were erroneous. If it would do so, he, for one, did he possess such a park, would gladly part with it to do away with poverty; but, in fact, population would swallow up such small gifts in a few years, and leave only fewer open spaces for all to enjoy. Emigration was good, but not rapid enough to relieve the pressure caused by rapid multiplication. The practical conclusion from all of which seemed to him to be, that Mr. Malthus was correct, and that, if ever we are to escape, as a nation, from poverty, it must be by the limitation of the size of our families. He (Lord Amberley) objected to celibacy; we all naturally objected to war and famine. Well, then, the only remaining alternative seemed to him to be small families; and after all it turned out to be a medical question how this could be best accomplished without injury to the health. He wished much he could hear the proposals of the medical men in the room as to the best means of limiting numbers. In America ladies were in the habit of keeping back their families, but the methods they employed seemed to him to be dangerous to health. Hence he should much like to hear a discussion as to whether some innocuous measure might not be discovered. It was remarkable that the subject should have first been taken up in America, where it was not so much required as it was here.

Mr. Rigby Smith believed that the existence of large families was an immense evil. He would add that, at present, it was by no means the best portion of the race which increased and multiplied too fast; it was precisely the opposite of this. Witness the celibacy of the barristers and of the upper and educated classes, and the rapid multiplication of the uneducated classes.

Dr. Charles Drysdale said he would not assume that all in the room agreed with the law of population, according to Malthus. He believed it was but proved by the following facts:—During the years from 1790 up to 1810, there was scarcely any emigration into the United States of America, and yet the population there nearly doubled itself in these twenty years. Now, in Great Britain the greatest rapidity of multiplication ever known —*i.e.*, from 1800 to 1853, had caused the population to double only in 53 years. In France the rate of increase of late was almost null. In Turkey it was calculated that it would require 555 years for the population, at its present rate of increase, to double itself. Now, it was evident that if in France, for example, the population did not double itself so fast as in the United States from 1790 to 1810, it must be because it was checked in various ways. And, on inquiry, it would be found that in France, as in England —(1). Marriages were contracted later than in America. (2). Wages were far lower in France than in the United States. (3). There were far more prostitutes in France than in the United States. (4). There were fewer children to a family in France than in England, or *a fortiori*, in the United States. Lastly, a vast number of children died from privations and poverty. He, therefore, admitted with Lord Amberley that the question was mainly a medical one—viz., how could married persons limit the number of their offspring without injuring their health? He thought this question required much calm thought and discussion, and meanwhile would only state that in France, a few years ago, he had in one hotel met with two young couples both married about five years, and both without children. On interrogation the same answer was returned by both husbands, that they were not rich enough yet to afford children. This was one solution of the difficulty of over-population, if not the best.

Mr. Nasmyth contended that the over production of children was, in a great measure, dependent on fashion. It was the present fashion in England to have large families, whilst in France, as everybody knew; a great number of persons thought it absolutely wrong to have more than two or three.

Mr. Davis contended that the cause of the poverty of the poorer classes in this country was not that they had too many children, but that the land laws were bad and required alteration.

We have reprinted above the most important portions of the debate, as it appeared in our issue of July 22nd. We understand that Lord Amberley, feeling that the views attributed to him are not likely to meet with favour with his friends in South Devon whom he desires to conciliate, denies the accuracy of the report.

We have only to say that we have entire confidence in the source from which we have received it; that it was revised by a gentleman who was present at the meeting; that Lord Amberley's official presence at the society, and the adoption by a subsequent speaker of the views which he now repudiates—should be some guarantee that his views were accurately represented; and that we believe our report embodies, if not his Lordship's *ipsissima verba*, at least the plain significance of his words.

We are not surprised that his Lordship should consider the obvious bent of the discussion such as to demand his repudiation. We take from it an unpleasant estimate of the prevailing morality of the age in which "advanced" politicians officiate at a discussion which, if it means anything, means abortion and prostitution as an expedient alternative for persons of easy conscience and unbridled appetite.

◆

Notes on Current Topics.

Doctors in the Legislature.

We hope we may accept the advancement of M. Nelaton and the rumoured intention of the Emperor to promote M. Claude Bernard to the Senate of France, together with the increased and increasing number of medical candidates for Parliamentary seats under the New Reform Act, as evidence of an awakening on the part of governments and the doctors themselves to the claims of the profession to legislative rank. The list of our existing medical members (if indeed they can be called medical representatives, in whom their professional connection is apparently forgotten) —Sir John Gray, Dr. Brady, and Dr. Clement—are numerously and energetically reinforced for the forthcoming contest by several other candidates. We have for the Universities of St. Andrews and Edinburgh, Dr. Prosser James and Dr. Richardson; for Manchester, Mr. Mitchell Henry, who at last election contested Woodstock; for Bridgewater, Mr. Vanderbyl; for Marylebone, Dr. Humphry Sandwith; for Colchester, Dr. Brewer; for Rochester, Dr. Alfred Smee, and we trust we may add Sir Dominic Corrigan to the list.

Whether any or many of these gentlemen succeed in obtaining a seat or not, we think their candidature is a matter for congratulation. Our profession owes its subordinate position, as we believe, mainly to the fact that its members are regarded by the public as "only mere doctors," simple earners of fees—Helots who have their task to do, and perform it and no more, and accordingly deserve little thanks for their services. It is satisfactory to see that the aspirations of our brethren are not limited, nor their ambition narrowed by the pursuit of their profession, and that even men who have practice to leave behind and fees to lose, are moved to some greater pursuit than medical money-getting.

The Quarterly Examinations at the Royal College of Surgeons in Ireland.

The second or Surgical Examination of the Royal College of Surgeons has just terminated, and it affords every reason for satisfaction to the College and the Profession.

The number of candidates was large—forty-eight applicants having appeared in the Hall. The answering was excellent, and in every respect bears favourable comparison with that elicited at the last quarterly examination. Of the entire number only two were rejected, and forty-six passed on much higher averages than have usually prevailed. We attribute this desirable condition of things to the justly severe measure meted out to the bad candidates on former occasions.

The Dublin City Prisons.

We rejoice to observe that the attempt to make the public appointments under the patronage of the Dublin Corporation subservient to family and religious considerations, to which we have more than once adverted, has been at last finally overthrown. The medical officer elected and re-elected by the Town Council under the circumstances which we have narrated, has been replaced by the officer elected by the Grand Jury, who formally entered on his duties last week. We cannot congratulate the public on the fact that they have achieved absolute purity of election in the new appointment, for the savour of a family political job is not much less offensive in the one case than in the other. Either gentleman is personally and professionally a perfectly unobjectionable occupant of the office; yet, were it not for the satisfaction that the attempted job of the Town Council, which was peculiarly flagrant in its character, has been defeated, we hardly think there is much choice of motives between the selection of a son-in-law for his father-in-law's, or a son for his father's politics.

Reproduction Extraordinary.

Our readers will call to recollection the fact that a young man who suffered under a repulsive deformity, exhibited himself some years since in the great towns of Great

Britain and Ireland, not only to the profession, but to the general public. He presented the extraordinary monstrosity of a third leg, and a double penis, and at the time a disgusting picture and a minute description of the appearances appeared in the columns of a leading medical periodical, and were so highly appreciated by a certain class that copies of the journal in question were sold at half-a-crown each. The only point of any scientific interest in the case was the influence of the monstrosity on the generative function, and we learn that some time since the young man was married at Cardiff, and that his wife has lately given birth to a fully formed and perfect child, which has since enjoyed uninterrupted health.

The Perils of the Sea-Side.

At a season when so many escape from the ordinary toils of life to spend a little time at the sea-side, a medical journal may well remind its readers of some of the perils that may be encountered, and are easily avoided. We are not about to dilate on the dangers of boating to those who cannot swim, although during this season four deaths have come under our personal notice caused by this carelessness. Nor do we propose to warn against the danger of entering apartments lately vacated by patients suffering from small-pox or other infectious disease; the recent Act of Parliament will, it is to be hoped, afford more protection from such perils than has heretofore been attainable. We have lately given some advice to bathers, and therefore need not dwell further on that subject, than to remark that during the past week we have met with a case rapidly ending fatally, induced by injudicious bathing.

Patients who so recklessly resort to such treatment without professional advice are just now so numerous that we can scarcely expect other than that some sad consequences should be occasionally met with.

We desire, however, to warn against perils more easily overlooked. There are many patients who, under the best advice, go to the sea-side and would obtain great benefit, but for their own imprudence. To say nothing of their diet, which, in many instances, is anything but suitable for them, they abandon every caution, and make demands on their slender strength which only the robust can endure.

Ladies who at home assert that a drive in the park fatigues them, that a northerly or easterly wind gives them cold, and that a drop of dew or rain might lay them up for weeks when they reach a fashionable watering-place, enter on a course of life that makes men wonder how they get through the toil. If a hurricane blow it is a "sea breeze," or a mere "land zephyr." If towards evening the seats on the parade should be dripping, it is "not pernicious dew or fog," but only the "sea moisture of the air settling." Should the sands be the fashion at the place selected, saturated shoes, stockings, and petticoats are of no consequence, as "sea-water never gives cold." Then excursions up precipitous hills, clambering up the cliffs, or jumping from rock to rock in the insane pursuit of all the hideous "wonders of the shore," that are demanded by the insatiable aquarium of an Englishwoman at the sea-side; these, and more than these, are the freaks constantly to be seen. For strong and hearty people, well and good! For those whose ailments are imaginary, better still a little roughing, it may do much to restore the tone of the over-wrought creature of civilisation, and give an appetite to the fastidious and dainty. But where there is real physical disease or defect, such freaks cannot be too sternly forbidden. Let us give an example. Palpitation may be a symptom that would disappear with fresh air and exercise, but suppose disease of one of the valves of the heart to exist—is there any medical man who could forget that the mode of life we have mentioned above would certainly aggravate it, and might rapidly prove fatal? Yet, we have known such patients exposed to such perils, and urged or dragged on in the mad career by friends and relatives, recklessly bent on making the most of the time. Sometimes the excess does not stop here, but balls and parties add ill-spent nights to over-wrought days. It is a great error. Let those who have committed it try a short time the effect of REST, and they will thank us for the hint.

Foreign Medical Literature.

ON DIABETES MELLITUS AND PARESIS OF THE RIGHT EXTREMITIES, IN CONSEQUENCE OF A TUMOUR IN THE MEDULLA OBLONGATA.

(Reported by Dr. J. B. Dompeling.)

Translated from the *Nederlandsch Archief voor Genees en Natuurkunde*, IVe Deel, Ie Aflevering, 1868, p. 179, by

W. D. MOORE, M.D.Dub. et Cantab., M.R.I.A., L.K.Q.C.P.I.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

The following case, already brought some weeks ago before the Medical Society of Utrecht, appears to me sufficiently important to be made known to a wider circle. From the explanation of the morbid phenomena in their details, in connection with the affection of the medulla oblongata, I refrain, confining myself rather to an accurate statement of the history of the case.

Heer v. L., born of a phthisical mother, had always enjoyed good, though not strong, health, and by observing a very regular course of life, and abstinence from Bacchus and Venus, he was never ill. He remembered having fallen, when at Zevenaar in his fifteenth year (1858), without any assignable reason or cause, upon his occiput, against a sharp angle of a wall. This was attended with no external injury, but with momentary loss of consciousness, and with the occurrence of a peculiar sensation in the right hand, while he felt a difficulty in walking. He afterwards suffered much from headache, commencing in front, and ending in the nape of the neck.

In his twenty-first year, he went as officer of health to India, having previously, though formerly thin, become, within a few months, rather corpulent. He arrived in good health in India, but thinks that he soon after found his gait to be tottering, and his vision double. In the course of six months he was, in July, 1865, transferred to Telok Betang, in the Lampongs, south coast of Sumatra. He there felt that the tottering in his gait increased, and that writing became difficult, as he could not guide the pen properly. On a certain morning he was attacked with fever, violent pain in the occiput, vertigo, and hiccough. These symptoms having been subdued after the lapse of 4½ days, he was directed to Katimbang, situated at the foot of Ratjabassa (highest mountain), a cooler place. The improvement which had set in did not, however, continue, so that he sailed for Batavia.

From the report of his state there made, the following appears:—

The patient has a suffering aspect. His face, especially on the right side, is of a dark red colour, the conjunctivæ are injected. The whole right side is somewhat paralysed. In the dark, or with his eyes closed, he cannot stand or walk without tottering considerably. In these respects he is better in the morning than in the evening. In the light he can better control his movements. The right, upper, and lower extremities are considerably emaciated, the muscles are flaccid. The difference in circumference between the right and the corresponding left side amounts to three Netherlands inches. The sense of touch in the right hand is almost lost, the sensibility to temperature on this side is, however, exalted.

As to the right lower limb, the feeling in the sole of the foot is normal, yet the patient complains of defect in guiding the foot, of difficulty in drawing on his stockings, of crackling in the right knee, of periodical spasms in the right foot and hand, while lying he can execute all movements with the right extremities. Under the action of the induction-current the irritability of the muscles of the right side seems to be diminished.

The patient complains moreover of giddiness when he lies low and when the temperature is high, of singing in both ears and double vision when he looks to a distance with his head raised, at which time the right eyeball is directed too much inward. When the head is bent forward, or looking at near objects, vision is normal. Ophthalmoscopic investigation presents nothing irregular, with the exception of slight hyperæmia of the retina.

His sleep is calm, without troublesome dreams. He has almost always pain in the occiput. Respiration is normal. The pulse is quick, more than 100 beats in the minute. The action of the heart is otherwise as it ought to be. Swallowing takes place almost invariably with the aid of fluids. His speech is undisturbed. So are the digestion, the sexual power, and the urinary apparatus. The patient complains only of considerable thirst, which constantly induces him to drink.

As to the psychical functions, he complains of weakness of memory, especially for the retention of names, while his temper is characterised by indifference and depression.

As he had expressed a wish for a cooler climate, he was removed to Sindanglaya, above Buitenzorg.

When there, he began to be more feverish in the evening; his pulse did not fall below 100 beats in the minute. On moving, his speech was affected with quivering of the lips, swallowing was very difficult. His left leg about the knee was insensible to pain and temperature. The right leg was paralysed. After a derivative treatment the congestive symptoms improved, but diarrhœa continued. At the end of a fortnight he returned to Batavia, used much laudanum for the diarrhœa (the cholera was then raging at Batavia), and ten days later embarked for Holland.

On the voyage home his condition became remarkably improved. He retained, however, a great appetite, particularly for sweets, and much thirst. He suffered a great annoyance from dryness of the eyes, labouring, in consequence, on two occasions, under conjunctivitis, and during the last weeks of his voyage he passed joints of a tapeworm. On the 21st December, 1866, he arrived here very happy at having, after so much wandering, reached a sure haven.

I saw the patient in the evening of the same day (21st of December, 1866). He was scarcely recognisable by those who had known him before his departure. He was decrepit, emaciated, I should almost say that he had become smaller. His unquenchable thirst for water struck me; I therefore had his urine examined the following morning, and it appeared that his disease, which in India had been diagnosed as progressive atrophic muscular paralysis, or progressive locomotor ataxy, was a considerable *diabetes.* The reaction of the urine was strongly acid. Its density was about 1·044 = 6°. With the copper-test fluid, one drop of urine in 60 of distilled water gave a very strong reaction. With the potash test, 10 drops of urine in two drachms of distilled water and half a drachm of liquor of caustic potash gave a brown reaction.

The weight of the body is 55 kilogrammes, or 110 pounds. The intellectual faculties are normal, both the imagination and the memory. Hearing on both sides is good, even acute. There is no tinnitus aurium.

Opthalmoscopical investigation, performed by Dr. Snellen, gave: paresis of all the muscles of the eye on the right side, especially of the abducent, thence double vision in all strong peripheral movements of the eyes, especially in looking outwards to the right. Slight nystagmus. Pupils easily movable, apparently somewhat less so towards the left. Emmetropia. Nothing else abnormal.

Smell and taste are good. The tongue does not deviate. The *right* half of the body, both arm and leg, and also in some degree the trunk, atrophied. The sense of touch is lessened. In the hand *two* sharp points of the compass could be distinguished only at a distance of about three Netherlands inches. The sensibility to temperature exalted. The whole *left* side better nourished, tolerably muscular and strong (the patient was from infancy left-handed). The sense of touch is normal, if not exalted, sensibility to pain and temperature diminished.

Respiration normal, often troubled with hiccough, pulmonary capacity ample. The voice masked. Neither abdomen nor hepatic region swollen or sensitive. Bowels rather confined, each evacuation accompanied with proglottides of a tapeworm.

The patient was now ordered as much as possible animal food, the use of Carlsbad water; subsequently he took also Vichy. The treatment of the tape-worm with Kousso was tried, whereupon a medio-cannellata of about three yards in length, without the head, appeared. Subsequently the treatment was repeated in Friesland, in vain, until later it completely succeeded with decoction of pomegranate, and the head also was expelled. Afterwards he used cod-liver oil, and had a seton placed in the back of the neck.

The patient now went to Zaandam, and some weeks later to Friesland, where he much enjoyed the country air. He sent me from time to time his urine, with statements. For example, January 19, 1867, took 110 ounces of fluid, while the quantity of urine was 152 medicinal ounces in the twenty-four hours. 2nd February, used 124, excreted 196 ounces, density 1·040. When diluted 450 times it still gives a very evident reaction with the copper test.

Beginning of March used 131, excreted 129 medicinal ounces.

Reaction very strongly acid; density 1·042 = 5¾ $^{\circ}/_{0}$

Returning on the 27th May from Friesland, I saw him again. His appearance was much improved; his weight was 118 pounds, he had therefore increased 8 pounds. He had now always written letters with the left hand, but the last, although very badly, again with the right. He stands more firmly on his legs, and totters only in the dark. His thirst is not so excessive. The eyes are still somewhat dry, only in the evening; but the urine still contains very much sugar, and its specific gravity is 1·045. He set out this day for Carlsbad; he got tired here and fancied the change might be of use to him. Though I did not expect a cure I thought it might improve his condition. After remaining there six weeks, under the treatment of Professor Seegen, he returned. He had first drunk of the Marcbrunnen, which caused diarrhœa, then of the Felsenquellen and Mühlbrunnen, subsequently of the Sprudel cold spring.

The urine at first contained 7$^{\circ}/_{0}$ of sugar.

The quantity in the 24 hours was 14 cups.

The following week the sugar was 4$^{\circ}/_{0}$ in 6 cups.

At the end of the treatment it was 2½$^{\circ}/_{0}$ in 6 cups, which may be called a small quantity.

The weight of the body is now 112 pounds, that is a falling off of 6 pounds; all the symptoms are better.

The strength, especially on the left side, is increased. The eyes are no longer so dry in the evening; the thirst is less. The double vision (images next one another) is very variable, at one time better and again worse.

The specific gravity of the urine is 1·035.

Within the last few days the cough has increased, with some tightness in the right side of the chest, and rusty-coloured sputa, especially in the morning.

The cough now began to get gradually worse. After the lapse of a couple of months hæmoptysis came on, and the patient became phthisical. In November the urine was once more examined by Dr. Brondgeest with Soleil's saccharometer. It contained then nearly 7$^{\circ}/_{0}$ of sugar, its specific gravity being 1·0195. The patient suffered much from fever, became very weak, and his life ended on the 2nd February, 1868. He had sat up that day for some hours, went to bed, fell asleep, and with a single gasp life was extinguished.

We have thus had to do, in this instance, with a very interesting case of diabetes. That this affection had a central origin, may almost certainly be stated, on account of the simultaneous occurrence of very serious cerebral phenomena. Indeed, I may say, that the diabetes was only one of the symptoms presented by the affection of the brain. It was at the same time the leading string to determine where this cerebral affection had its seat, which in fact could not be otherwise than on a level with the fourth ventricle. Disease, however, of this part of the brain, is attended with this form of diabetes, which Eulenberg and Landois have described as the angio-neurotic form of diabetes. I borrow the following from their important communications, to be found recapitulated in a series in the *Wiener Wochenschrift* for the 30th November, 1867:—

"As is well-known, Claude Bernard made the important discovery, that an injury of the floor of the fourth ventricle of the brain is followed by the excretion of sugar through the urine, which in mammalia commences one and a half hours after the operation, and for the most part terminates in six hours. The place on the floor is tolerably extensive, and on opposite sides of the median line. If the lesion touches the spot between the origins of the vagi and auditory nerves, we observe with the excretion of sugar increased secretion of urine ; if it be higher, the excretion of urine, and also the quantity of sugar, is more moderate, but there is at the same time albumen in the urine. Through the operation, the so-called sugar puncture, the centre of the vascular nerves of the liver becomes injured, and there arises in fact an angio-neurotic form of diabetes.

"According to Schiff, the paths of these vasomotor nerves of the liver run from the floor of the fourth ventricle in the medulla oblongata, and further in the anterior columns of the cervical and dorsal medulla, to the fourth or fifth dorsal vertebra. Here they leave the medulla and repair through the communicating branches in the path of the sympathetic, run with them downwards, and finally accompany the vessels of the liver in the hepatic plexus, into the interior of the parenchyma.

"Some of these nerves seem to take their course in the path of the splanchnic nerve, at least, von Graefe and others saw diabetes occur after division of this nerve. In general lesion of the vasomotor hepatic nerves has, in whatever part of their course, the same result as the sugar puncture. There always arises, as immediate result, paralytic vascular dilatation of the liver with stasis.

"In the interior of the hepatic cells the so-called hepatic starch or glycogen is found, a non-nitrogenous substance which is by ferments, and also by saliva, metamorphosed into sugar, which, however, does not take place in the normal state.

"The sugar formed by fermentation is diffused through the blood-vessels in the blood. A portion of the sugar is in the lungs burned through respiration into carbonic acid, so soon, however, as the quantity of sugar in the blood amounts to one-half per cent, the combustion no longer takes place completely, and sugar appears in the urine.

"This sort of diabetes may now be traumatic : diabetes angio-neuroticus traumaticus, or toxical.

"The first runs mostly an acute course, after a fall on the occiput, wounds of the head, contusion of the neck ; but also mental affections. &c., may act injuriously on the centre of the hepatic vascular nerves."

What was the nature of the cerebral affection in the above case, and what cause had given rise thereto ? There was as little reason for assigning the first as the second. On the other hand, there were many reasons for believing that in this instance pressure had taken place, from some tumour or other, in the neighbourhood of the fourth ventricle.

As to the cause, two presented themselves as having possibly given rise to the disease. In the first place, the fall on his head in the patient's fifteenth year, which, as we have seen, is frequently the cause of this form of diabetes. But if we assume this cause, the results thereof were very insidiously and slowly developed; for from that time until the patient went to India no trace of any cerebral affection manifested itself. All that time I saw the patient daily, and went about with him. His intellectual faculties, his vegetative and animal functions were perfect.

Another question which might come under consideration was whether there was any connection between the occurrence of the tænia and the cerebral lesion; and I must acknowledge that at first at least I attached some value to it.

The possibility of so-called self-infection is, however, rendered probable by many observations. Not long since I met with in "Schmidt's Jahrbücher," 1867, No. 3, a case described by R. Wagner, in which cysticerci in the brain and a tænia in the jejunum co-existed. Among the eighty-eight cases of cysticerci in the brain collected by Küchenmeister, however, I found not one in which they were located in the fourth ventricle. Meanwhile, this appeared to me to be no great difficulty, as there was, *a priori*, no conceivable reason why cysticerci should not occur in that place. Though, if in our patient self-infection had taken place, we should assume that cysticerci of tænia mediocanellata may occur in the brain, which, so far as I know, has not yet been met with.[1]

But enough of conjectures. The post mortem examination, at least of the skull, was permitted. A tumour was found occupying the whole right half of the medulla oblongata, and passing into this without any defined line of demarcation. Above and on the under surface of the tumour were situated two vesicles filled with fluid, in which, however, nothing of cysticerci was met with. Otherwise the brain was normal; only some turbid fluid was found between the pia mater and arachnoid.

The tumour, further examined by Prof. Koster, is a sarcoma fuso-cellulare, with great capillary vascular developments; while in some places nothing but fibrillar connective tissue with blood-vessels is met with. Nowhere is any carcinomatous structure to be found.

The tumour, which is of the size of a small walnut, was evidently formed beneath the pia mater. This membrane can be traced from its circumference into the neighbourhood of the tumour, after which it passes into the surface of the same, without being capable of being further separated.

On longitudinal incision made through the tumour we can find absolutely no boundary between the nerve-tissue of the medulla and the sarcoma. Each passes undistinguishably into the other; yet, evidently, rather displacement of the mass of the medulla has occurred than a taking-up of this latter into the tumour, as nowhere in this is nerve-tissue met with, except in the depth of the incision, where it is doubtful whether we have the tumour or the medulla before us.

[Representations of the tumour are given in the original, from which it appears] that the tumour has strongly pushed to the left the sulcus longitudinalis from the floor of the fourth ventricle; that the roots of the accessory nerve of Willis, and the inferior root of the nervus vagus of the right side, *highly atrophic from the tumour itself*, come outwards, and that the fibres of origin of the auditory and facial nerves were uninjured.

In conclusion, I must add that just as I was writing out this case I found one nearly precisely similar communicated in Virchow's Archiv,[1] and described as a great peculiarity, almost as a curiosity. The tumour examined by Virchow was also in that case a sarcoma fuso-cellulare.

◆

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

MEETING AT NORWICH, AUGUST, 1868.

THE 1868 meeting will rank second to none of its predecessors for the interest and importance of its numerous addresses and papers. A detailed report of the proceedings would occupy many numbers of our journal. We propose, therefore, with a view of economising space, to give mere extracts from, or abstracts of, a few of those we judge may be acceptable to our readers.

PROFESSOR TYNDALL'S ADDRESS.

The section devoted to Mathematical and Physical Science was opened by an address from Professor Tyndall, who presided over this section. The learned successor of Faraday at the Royal Institution, after an introduction of great length, proceeded as follows :—"There have been writers who affirmed that the pyramids of Egypt were the productions of nature ; and in his early youth Alexander Von Humboldt wrote an essay with the express object of refuting this notion. We now regard the pyramids as the work of men's hands, aided probably by machinery of which no record remains. We picture to ourselves the swarming workers toiling at those vast erections, lifting the inert stones, and, guided by the volition, the skill, and possibly at times by the whip of the architect, placing the stones in their proper positions. The blocks in this case were moved by a power external to themselves, and the final form of the pyramid expressed the thought of its human builder. Let us pass from this illustration of building power to another of a different kind. When a solution of common salt is slowly evaporated, the water which holds the salt in solution disappears, but the salt itself remains behind. At a certain stage of concentration the salt can no longer retain the liquid form ; its particles, or molecules, as they are called, begin to deposit themselves as minute solids, so minute, indeed, as to defy all microscopic power. As evaporation continues solidification goes on, and we finally obtain, through the clustering together of innumerable molecules, a finite mass of salt of a definite form. What is this form ? It sometimes seems a mimicry of the architecture of Egypt. We have little pyramids built by the salt, terrace above terrace from base to apex, forming thus a series of steps resembling those up which the Egyptian traveller is dragged by his guides. The human mind is as little disposed to look at these pyramidal salt-crystals without further question, as to look at the pyramids of Egypt without inquiring whence they came. How, then, are those salt-pyramids built up? Guided by analogy you may suppose that, swarming among the constituent molecules of the salt, there is an invisible population, guided and coerced by some invisible master, and placing the atomic blocks in their positions. This, however, is not the scientific idea, nor do I think your good sense will accept it as a likely one. The scientific idea is that the molecules act upon each other without the intervention of slave labour; that they attract each other and repel each other at certain definite points, and in certain definite directions; and that the pyramidal form is the result of this play of attraction and repulsion. While, then, the blocks of Egypt were laid down by a power external to themselves, these molecular blocks of salt are self-posited, being fixed in their places by the forces with which they act upon each other. But passing from what we are accustomed to regard as a dead mineral to a living grain of corn. When it is examined by polarised light chromatic phenomena similar to those noticed in crystals are observed. And why? Because the architecture of the grain resembles in some degree the architecture of the crystal. In the corn the molecules are also set in definite positions, from which they act upon the light. But what has built together the molecules of the corn? I have already said regarding crystalline architecture that you may, if you please, consider the atoms and molecules to be placed in position by a power external to themselves. The same hypothesis is open to you now. But if in the case of crystals you have rejected this notion of an external architect, I think you are bound to reject it now, and to conclude that the molecules of the corn are self-posited by the forces with which they act upon each other. It would be poor philosophy to invoke an external agent in the one case and to reject it in the other. Instead of cutting our grain of corn into thin slices and subjecting it to the action of polarised light, let us place it in the earth and subject it to a certain degree of warmth. In other words, let the molecules, both of the corn and of the surrounding earth, be kept in a state of agitation; for warmth, as most of you know, is, in the eye of science, tremulous molecular motion. Under these circumstances, the grain and the substances which surround it interact, and a molecular architecture is the result of this interaction. A bud is formed; this bud reaches the surface, where it is exposed to the sun's rays, which are also to be regarded as a kind of vibratory motion. And as the common motion of heat with which the grain and the substances surrounding it were first endowed enabled the grain and these substances to coalesce, so the specific motion of the sun's rays now enables the green bud to feed upon the carbonic acid and the aqueous vapour of the air, appropriating those constituents of both for which the blade has an elective attraction, and permitting the other constituent to resume its place in the air. Thus forces are active at the root, forces are active in the blade, the matter of the earth and the matter of the atmosphere are drawn towards the plant, and the plant augments in size. We have in succession the bud, the stalk, the ear, the full corn in the ear. For the forces here at play act in a cycle which is completed by the production of grains similar to that with which the process began. Now, there is nothing in this process which necessarily eludes the power of mind as we know it. An intellect the same in kind as our own would, if only sufficiently expanded, be able to follow the whole process from beginning to end. No entirely new intellectual faculty would be needed for this purpose. The duly expanded mind would see in the process and its consummation an instance of the play of molecular force. It would see every molecule placed in its position by the specific attractions and repulsions exerted between it and other molecules. Nay, given the grain and its environment, an intellect the same in kind as our own, but sufficiently expanded, might trace out *a priori* every step of the process, and by the application of mechanical principles would be able to demonstrate that the cycle of action must end, as it is seen to end, in the reproduction of forms like that with which the operation began. A similar necessity rules here to that which rules the planets in their circuits round the sun. You will notice that I am stating my truth strongly, as at the beginning we agreed it should be stated. But I must go still further, and affirm that in the eye of science *the animal body* is just as much the product of molecular force as the stalk and ear of corn, or as the crystal or salt of sugar. Many of its parts are obviously mechanical. Take the human heart for example, with its exquisite system of valves, or take the eye, or the hand. Animal heat, moreover, is the same in kind as the heat of a fire, being produced by the same chemical process. Animal motion, too, is as directly derived from the food of the animal, as the motion of Trevethyck's walking-engine from the fuel in its furnace. As regards matter the animal body creates nothing; as regards force it creates nothing. Which of you by taking thought can add one cubit to his stature? All that has been said regarding the plant may be re-stated with regard to the animal. Every particle that enters into the composition of a muscle, a nerve, or a bone, has been placed in its position by molecular force. And unless the existence of law in these matters be denied, and the element of caprice introduced, we must conclude that, given the relation of any molecule of the body to its environment, its position in the body might be predicted. Our difficulty is not with the quality of the problem, but with its complexity; and this difficulty might be met by the simple expansion of the faculties which man now possesses. Given this expansion, and given the necessary molecular data, and the chick might be deduced as rigorously and as logically from the egg as the existence of Neptune was deduced from the disturbances of Uranus, or as conical refraction was deduced from the undulatory theory of light. You see I am not mincing matters, but avowing nakedly what many scientific thinkers more or less distinctly believe. The formation of a crystal, a plant, or an animal, is in their eyes a purely mechanical problem, which differs from the problems of ordinary mechanics in the smallness of the masses and the complexity of the processes involved. Here you have one-half of our dual truth; let us now glance at the other half. Associated with this wonderful mechanism of the animal body we have phenomena no less certain than those of physics, but between which and the mechanism we discern no necessary connection. A man, for example, can say, I feel, I think, I love; but how does consciousness infuse itself into the problem? The human brain is said to be the organ of thought and feeling; when we are hurt the brain feels it, when we ponder it is the brain that thinks, when our passions or affections are excited it is through the instrumentality of the brain. Let us endeavour to be a little more precise here. I hardly imagine that any profound scientific thinker who has reflected upon the subject exists who would not admit the extreme probability of the hypothesis, that for every fact of consciousness, whether in the domain of sense, of thought, or of emotion, a certain definite molecular condition is set up in the brain; that this relation of physics to consciousness is invariable, so that, given the state of the brain, the corresponding thought or feeling might be inferred; or, given the thought or feeling, the corresponding state of the brain might be inferred. But how inferred? It is at bottom not a case of logical inference at all, but of empirical association. You may reply that many of the inferences of science are of this character; the inference, for example, that an electric current of a given direction will deflect a magnetic needle in a definite way; but the cases differ in this, that the passage from the current to the needle, if not demonstrable, is thinkable, and that we entertain no doubt as to the final mechanical solution of the problem; but the passage from the physics of the brain to the corresponding facts of consciousness is unthinkable. Granted that a definite thought and a definite molecular action in the brain occur simultaneously; we do not possess the intellectual organ, nor apparently any rudiment of the organ, which would enable us to pass by a process of reasoning from the one phenomenon to the other? They appear together, but we do not know why. Were our minds and senses so expanded, strengthened, and illuminated as to enable us to see and feel the very molecules of the brain; were we capable of following all their motions, all their groupings, all their electric discharges, if such there be; and were we intimately acquainted with the corresponding states of thought and feeling, we should be as far as ever from the solution of the problem, "How are these physical processes connected with the facts of consciousness?" The chasm between the two classes of phenomena would still remain intellectually impassable. Let the consciousness of love, for example, be associated with a right-handed spiral motion of the molecules of the brain, and the consciousness of hate with a left-handed spiral motion. We should then know when we love that the motion is in one direction, and when we hate that the motion is in the other; but the "why?" would still remain unanswered. In affirming that the growth of the body is mechanical, and that thought, as exercised by us, has its correlative in the physics of the brain, I think the position of the "materialist" is stated as far as that position is a tenable one. I think the materialist will be able finally to maintain this position against all attacks; but I do not think, as the human mind is at present constituted, that he can pass beyond it. I do not think he is entitled to say that his molecular groupings and his molecular motions explain everything. In reality they explain nothing. The utmost he can affirm is the association of two classes of phenomena, of whose real bond of union he is in absolute ignorance. The problem of the connection of body and soul is as insoluble in its modern form as it was in the prescientific ages. Phosphorus is known to enter into the composition of the human brain, and a courageous writer has exclaimed, in his trenchant German, "Ohne phosphor kein Gedanke." That may or may not be the case; but even if we knew it to be the case, the knowledge would not lighten our darkness. On both sides of the zone here assigned to the materialist he is equally helpless. If you ask him whence is this "matter" of which we have been discoursing, who or what divided it into molecules, who or what impressed upon them this necessity of running into organic forms, he has no answer. Science also is mute in reply to these questions. But if the materialist is confounded and science rendered dumb, who else is entitled to answer? To whom has the secret been revealed? Let us lower our heads and acknowledge our ignorance one and all. Perhaps the mystery may resolve itself into knowledge at some future day. The process of things upon this earth has been one of amelioration. It is a long way from the Iguanodon and his contemporaries to the president and members of the British Association. And whether we regard the improvement from the scientific or from the theological point of view, as the result of progressive development, or as the result of successive exhibitions of creative energy, neither view entitles us to assume that man's present faculties end the series—that the process of amelioration stops at him. A time may, therefore, come when this ultra-scientific region by which we are now enfolded may offer itself to terrestrial, if not to human investigation. Two-thirds of the rays emitted by the sun fail to arouse in the eye the sense of vision. The rays exist, but the visual organ requisite for their translation into light does not exist. And so from this region of darkness and mystery which surrounds us, rays may now be darting which require but the development of the proper intellectual organs to translate them into knowledge as far surpassing ours as ours does that of the wallowing reptiles which once held possession of this planet. Meanwhile the mystery is not without its uses. It certainly may be made a power in the human soul; but it is a power which has feeling, not knowledge, for its base. It may be and will be, and we hope is, turned to account, both in steadying and strengthening the intellect, and in rescuing man from that littleness to which, in the struggle for existence, or for precedence in the world, he is continually prone.

MR. BROWN'S ADDRESS.

The section of Economic Science and Statistics was presided over by S. Brown, Esq., President of the Institute of Actuaries. In his address he referred to the subject of technical education, to which he considered a strong impulse had been given by the comparisons of the world's industry occasioned by the various exhibitions held of late years. It was clearly necessary that a higher standard of general education should be established among our people, and a conference called together by the Society of Arts had brought together a large number of statesmen and men of science on the subject. It appeared to be desirable that scientific instruction should be followed by technical education in workshops; and a great advance would be made if employers required more proofs of practical knowledge. It was proposed that children should attend longer at school. The question arose whether this would affect the labour market, or whether a compensation would be found in the increased skill attained. The recent munificent gift of Mr. Whitworth deserved the hearty thanks of the nation, and might be expected to give a great impulse to the movement generally. That there was already a large number of skilled workmen in this country might be seen in the interesting volume recently published by the men sent to the Paris Exhibition by the Society of Arts. Upon the whole, it would seem as if the action of the government would be best exerted by extending grants in aid of local subscriptions, by appointing lecturers, or by aiding new school buildings, while a system of endowments would probably produce satisfactory results. Upon the question of labour and capital, it really appeared as if some progress had been made during the last year in the solution of this difficult question. It would seem that a better knowledge of the principles of political economy and the laws which regulated the production and distribution of wealth would be beneficial to all parties. It was earnestly to be hoped that strikes, which occasioned so much ill-feeling and loss of wages, would be more and more avoided. The system of *conseils des prudhommes* and courts of conciliation had been attended with beneficial results. Some system of industrial partnerships appeared likely to unite both workmen and employers, and would enable the former to inquire into the state of markets and foreign competition. The president traced with satisfaction the progress of insurance—life, fire, and marine. With regard to life insurance, vital statistics had now assumed a form which enabled the most complicated problems of human life to be dealt with; but life insurance business appeared to be making greater progress in the United States than in Great Britain. The progress of the Post-Office in this country might be regarded as a proof of the growth of education; and the enlightened readiness with which every improvement was adopted by the Post-Office gave us reason to hope that what many regarded as an unwarrantable interference with private enterprise—viz., the purchase by the State of telegraph property, would prove a public benefit. It seemed probable that a uniform charge of 6d. per message would be established, and the consequence would be advantageously felt in the internal trade of the country and in the promotion of private convenience. As it might be assumed that telegraphic business expanded at the rate of 10 per cent. per annum, he believed that the interest of the capital to be paid for the purchase of the telegraphs would gradually be more than covered. The president next touched on the desirability of establishing a uniform system of weights and measures, and on the equally difficult question of monetary unity. As regards the latter subject he remarked that Austria and the Papal government had expressed a readiness to take up the subject, and it seemed strange that when the Papal government was ready to act in the matter the English government did nothing. Finally, the president alluded to the international statistical conference, and he remarked that the effect of this congress was seen in the great importance now attached to the collection of government statistics of all kinds which would throw light on the many unsolved problems of the age.

MR. BIDDER'S ADDRESS.

In the Mechanical Science section, Mr. G. P. Bidder, C.E., occupied the chair. In opening the section, he said they had to consider the operations of the laws of mechanics with a view to benefit the world in general, and this country in particular. The laws they applied were certain and sure, and there was no doubt that in their application they would conduce to the happiness of mankind in general. He referred to some of the principal topics engrossing public attention in the present day, and, noticing first the great water question, he congratulated the committee on having present some of the greatest and most eminent authorities upon that subject, who would, doubtless, give information that the association would diffuse for the benefit of the public in general with reference to the supply and utilisation of water in various ways, and preserving rivers from pollution by sewage and the refuse from manufactories. A more beautiful and interesting subject than the habits of rivers could not engage the attention of engineers; and whether they looked at the circumstances of the constitution of the great rivers of India and America, or came down to those in their own neighbourhood, they would find that the same general laws pervaded all. It was well-known that the greatest rain-fall took place at the highest levels. At the top of the Himalayas the rain-fall was not less than 400 inches per annum, while on some of the mountains of Cumberland it was 200 inches, but in Norfolk only about 20 inches. He suggested that the quantity of water that fell on the whole course of a river should be gauged, and that observations should be taken to show the meteorological conditions of the atmosphere under which it fell. If that course were pursued, a body of facts would be brought together which he thought might be applied for the benefit of the country to a very great extent. He next referred to the peculiar characteristics of the rivers in the neighbourhood—viz., the Wensum, the Yare, the Waveney, and the Bure, and spoke of the influence these were supposed to have in maintaining the bar at Yarmouth. He regretted that tidal observations which could easily have been obtained from Yarmouth and Lowestoft, had not been laid before the Association; and expressed his belief that a thorough investigation and careful collection of facts would show that the land-water gave little, if, indeed, any advantage to the port of Yarmouth, and that a large extent of land now rendered almost unproductive by flood waters might be utilised without damage to that port.

Speaking of the Suez Canal, which was now approaching completion, he referred to the fact that it would be necessary to fill certain lakes in the vicinity of the canal (which were now dry) from the Red Sea, which was distant eighteen miles; and as these lakes covered an area estimated by some at 300 square miles, and evaporation went on in Egypt at the rate of one inch per diem, the evaporation from the lakes would be equal to 3,600,000,000 cubic feet per diem, or 250,000 cubic feet per minute. As soon as this canal was opened he thought the association should be put in possession of all the phenomena attendant upon its opening, for he could not help thinking that it must exercise some influence upon the atmosphere of the adjoining district, which would be worthy the attention of the association. He next approached a question which, he said, had excited a great deal of public attention—viz., the state of the British navy; and he might begin by saying that however satisfactory that state might be to some departments it was not satisfactory to the country in general. He would endeavour to point out in what way public opinion might be brought beneficially to bear upon this important subject. They would, no doubt, all agree with him that they had all but one desire—viz., that this country—whatever might be the cost—should have the best ships that the ocean could carry and that machinery could propel. With regard to the ships, he thought the great source of the present unsatisfactory state of things was the total absence of any system upon which their construction was conducted. Before building their ironclad navy it should have been considered what they were to be filled with, according to the plan adopted in the merchant service. They should also determine before a vessel was built what its speed would be, and no ship should be considered a success that did not accomplish a sea-going speed; while all should be as nearly as possible of the same speed, in order to enable them to act efficiently. He did not purpose entering into the relative merits of broadside guns and turret guns, but he would say that whatever difficulty there might be in getting fine lines with broadside guns that difficulty did not exist in the case of turret ships. Another point was that at present they did not know until they sent a ship to sea to what extent she was going to roll; but the mechanical principles upon which this depended under ordinary circumstances were so well known, that the extent to which a ship would roll should be known before a quarter of a million of money was spent upon her. The trials, of ships in Stokes Bay he characterised as a sheer delusion and said that trials to be of any value, should be conducted at sea, by men independent of any department, or of any other influence whatever; and until that was done they would not be able to bring to bear such a check upon the Admiralty department as the country had a right to demand. With regard to the armour of ships, he contended that this was a subject that should be subordinate to the considerations he had mentioned, for it was of no use to have a ship so overweighted that she became useless as a movable fort. He concluded his address by some remarks on technical education (contending that it should comprise a sound knowledge of the elemental laws of mechanics, and be specially directed to the position the student was to fill in life), and on the application of machinery to the economical working and ventilation of mines.

CAPTAIN RICHARDS'S ADDRESS.

The chair was taken in the Geographical Section by Captain Richards, R.N., who in the course of his interesting address said:—It cannot be long before a cable is laid through the centre of the Mediterranean Sea, connecting Gibraltar with Malta, Malta with Alexandria, and Alexandria by the Red Sea with India. Then, again, I think the time is not far distant when the connection between India and China, and between India and Australia will be completed. These great undertakings require accurate knowledge and an amount of skill, patience, and perseverance on the part of both the engineer and the seaman which those who are not thoroughly acquainted with the subject but little understand. Our energies and efforts, therefore, have been directed lately to this subject; and by the aid of science and the modern mechanical appliances which science has produced, instead of the vague and imperfect knowledge which we possessed up to a comparatively recent period, we are now intimately acquainted with the depths of almost all the oceans on the globe. For myself, I consider that these great results are second to none which have been obtained in geographical research during the past few years; perhaps I may say that they are of greater practical importance. To follow up the progress of geographical discovery from the earliest times, over the whole of Europe and the greater part of North and South America, geography has comparatively little left to learn. In Asia, too, over the great empires of China and Japan, there is no reason to doubt that geography has been well understood and cultivated, although from the peculiar institutions and customs of those countries, and from the jealousy of rulers and other causes they have been shut out to a great extent from the observation and enterprise of Europeans. Then on that great neutral ground in Central Asia, between the northern boundaries of India, and the southern parts of Russia, and in Western China and Tartary, which has been attracting a great deal of attention lately, we have yet a great deal to learn. At the same time, owing to the zeal and enterprize of our Indian officers, on the one side, and of the Russian armies of exploration—some call them encroachments—on the other, we are learning something every year. It is only a few weeks since that a traveller left these shores under the auspices of the Geographical Society in search of further discovery in these regions. Again, with the geography of those great groups of islands which are spread over the Pacific and the Indian Oceans, we are tolerably well acquainted, owing to maritime discovery, aided by the labours of the Church missions, which have invariably taken a very important part in all such matters. But now we must turn to another side of the subject, and it must be confessed that it is the darker side. If we turn to Africa, to Australia, New Guinea, Borneo, or to the Arctic regions, there the mind almost fails to comprehend the great problems that geography has yet to solve; and it is almost sickening to reflect how comparatively little we have learnt from all the great efforts and sacrifices that have been made by individual explorers both in our own time and in past times. Let us look at Australia. Here a great English nation has grown up within the present century, and yet there is scarcely more than a corner of that continent which can be said to be fairly occupied. With its sea coasts alone, and not even with all those are we thoroughly acquainted. Of the greater portion of its vast interior, it is scarcely an exaggeration to say that we know little more than we did when Cook first visited its shores a hundred years ago. The question seems to arise, to what cause are we to attribute the small success which has hitherto attended the labours of the explorers in that region, many of whom have given up their lives to the cause? Certainly, there has been no want of zeal, or enterprize, or devotedness on their part. It may be that their undertakings are too great for individual enterprise, or, indeed, for any enterprise not under the direct auspices of Government; perhaps means and resources may have been wanting, or organisation, or combination; but, be the cause what it may, it is certain that no efforts have yet been made at all commensurate with the importance of the undertaking, or the importance of the results which are to be expected from them. It does seem to me that the time has come when some combined effort should be made to wipe away what almost appears a reproach to geography. Indeed, lately a proposal has been made for an organised exploration of the interior of Australia, which probably is known to many here. This proposal emanated from Dr. Neumeyer, who has become an Australian, and who is well-known in the scientific world. It has received the support and approbation and countenance of the Geographical Society. But I am afraid the Geographical Society has not much more than its sympathy to give. It is to be hoped that if the attempt is ever undertaken, it will be done under Government auspices; with such an organization as to leave failure almost out of the question. There is another *terra incognita*, New Guinea, which is almost within sight of the northern shores of Australia. The coasts of that great island have scarcely been correctly laid down on our maps. Navigators of various countries have landed upon them, but I am afraid the time is still distant when this very interesting country has any chance of being opened up and civilized. Its very extent, and the hostility of native tribes and various other causes, place it entirely without the limit of any individual enterprise, and no country seems yet disposed to put its mark upon it. I should not like to leave these southern regions without saying a few words on one of the latest and most flourishing acquisitions of the British Crown—I mean New Zealand. As an instance of rapid geographical discovery and of colonization almost coincident with it, this is, perhaps, the most remarkable instance in the history of the whole world. Scarcely thirty years ago almost the sole occupants of New Zealand were a few English missionaries, who have generally been the pioneers of civilization in those distant countries. Some ten years later, Lord Auckland, then at the head of the navy, foresaw that the easiest and shortest mode of success in New Zealand was a complete exploration of all its shores. This was undertaken under his auspices, and completed within seven years. During this period colonization advanced very rapidly; and at the present time, in spite of many difficulties from native wars, the islands of New Zealand are inhabited throughout their length and breadth by Englishmen and Englishwomen, in possession of all the comforts and prosperity of an old and long settled country. There is one incident connected with New Zealand which is, perhaps, not generally known. It is this—that but for the accidental presence of a little brig of war there in 1839 or 1840, commanded by the late Captain Owen Stanley, the greater part of New Zealand, certainly the fairest part of it, would now have been under the flag of another country, and we should have had the spectacle, probably, of a second British Channel at the antipodes, with our neighbours looking at us across Cook's Straits. I will now turn very briefly to Africa, fruitful certainly, if in nothing else hitherto, in geographical adventure and daring. It is a mighty subject, too vast almost to be discussed on this occasion, and the few words that I shall have to say about Africa will be confined to an object of great interest to all Englishmen—that is, the fate of Livingstone, whose life has been so intimately associated with Africa, and who for the last two years and a-half has been wandering almost single-handed through that great continent in pursuit of the object to which his life has been mainly devoted. With regard to having work to do, Livingstone's absence may be most satisfactorily accounted for. But the least hopeful part of the question to me is that we have heard nothing from him at Tanganyika. This may be accounted for by the non-arrival of caravans; still his silence is matter of great anxiety. If he should be spared to return to this country, I believe he will return by the way he went. At any rate, I do not see that anything can be done in the way of searching for him until something more is heard from him. The only thing, indeed, that can be done would be to ascertain beyond a doubt whether he has ever reached the eastern side of Tanganyika lake; this might probably be done from Zanzibar, and I think it ought to be done. In the course of a few further observations, Captain Richards called attention to the proposed exploration of the peninsula of Sinai, and then urged the importance of carrying out an overland communication between Canada and British Columbia, in view of the great exertions being made by the United States to cross the entire continent from the Atlantic to the Pacific by railway.

THE SOIREE.

The grand *soiree* was held in St. Andrew's Hall, a very spacious building, having the appearance of a church; it has within the last few years been restored and decorated at considerable expense, and around it are hung a fine collection of portraits of Norfolk and Norwich worthies, besides a few paintings of historical interest. Near the orchestra, all the costly and beautiful corporate regalia of the city of Norwich, formed a gorgeous display; on another table near, Dr. Graham, Master of the Mint, exhibited a voltameter, the negative electrode of which is formed by a bar of palladium. When contact is made with a battery oxygen gas is freely evolved from the positive pole, but some seconds elapse before hydrogen rises from the palladium or negative electrode. This non-evolution of gas proves that it is absorbed by the metal, and the absorption is made evident by the expansion of the rod to the same extent as if it had been heated to redness, and the elongation of the bar, acting on a lever, causes an electric bell to ring. On reversing the poles of the battery oxygen was evolved from the palladium bar, removing the hydrogen previously absorbed by the metal, which then returned to its former dimensions. Dr. Graham's previous experiments have proved that palladium absorbs nearly 900 times its volume of hydrogen, which may be extracted by heating *in vacuo*. In the centre of the hall was placed a very interesting collection of war *matérial*, shown by Her Majesty's War Department. It comprised many of the novelties recently brought into operation in Abyssinia, including a specimen of a 7-pounder mountain-gun; also a model of an Armstrong gun, and of Captain Moncrieff's projecting barbette carriage; specimens of the Palliser and other shells, Boxer's parachute shell-rocket, rocket tubes, sectional models of guns, &c. In one of the ante-rooms in the same department was exhibited a fine collection of photographs connected with gunnery, the most interesting being those showing the effect of shots upon armour-plating. Mr. W. Ladd, of London, exhibited a new magnetic machine of great power, and some magnificent specimens of Iceland spar. On a table near the orchestra were cases containing extensive and beautiful geological specimens, British land and freshwater shells, fossils from the chalk and gravel beds in the vicinity of Norwich, a volume of beautifully coloured sketches of African scenery, and a model of the Victoria falls on the Zambesi river, South Africa, which in extent completely eclipse the celebrated Niagara, being 1900 yards wide, and 400 feet deep, the width of the Niagara being only 1000 yards and their depth 150 feet. Mr. Frank Buckland, the eminent naturalist, exhibited a number of piscatorial specimens, including a plaster-cast of a monster pike, weighing 28 lb., which was caught in the Thames a short time since. At intervals around the hall ten members of the Norwich Microscopical Society gave to the public an opportunity of examining the wonders revealed by the microscope. The objects exhibited included anatomical preparations (sections of tongue, skin, lungs, and brain), the cell circulation of plants, the water flea, specimens of insect anatomy, wings and wing cases, diatomacia, foraminifera, vegetable alkalides, &c. Mr. J. Huggins, of Norwich, showed a polarising kaleidoscope, invented by himself, giving colours so gorgeous as to be quite unapproachable by any known process of artificial colouring. There was likewise a very interesting collection of drawings of fossil crustacea, and a series of beautiful photographs of buildings and other objects of interest in Norwich and the neighbourhood, shown by Mr. Sawyer, of that city.

◆

Correspondence.

"THE FELLOWSHIP OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your "Notes on Current Topics" in No. 8 of your Journal are before me. The second of these, headed "The Fellowship of the Royal College of Physicians," suggests to the reformer the propriety of "giving the body of Fellows at large the opportunity of proposing names" (of Members) "for promotion." Without doubt this would be a very important and material advance on the present plan, which, as you are well aware, permits the "Council" to "*be all-powerful in promoting its friends.*" If, however, it be true that the time has now "*come for a change in the mode of selection*" of Members of the College in Pall Mall to the Fellowship, it is essential that the kind or character of such change should not be determined prematurely. Furthermore, if the acceptance by the Profession of large and liberal views—and the very evident necessity of a sure and abiding adaptation of such views to the governments of our several Colleges of Physicians and Surgeons, &c., are no idle chimeras—then is there good reason why some of us "*outsiders*" should be allowed the utterance of a few words in regard to the question herein raised.

Now, there appear to my mind three modes of action open to the reformer, or, if you please, to the law-givers of the London College of Physicians. These are—

1st. The adoption of a bye-law, whereby any individual Fellow may be permitted, in some defined and approved way, to name to the Council, through the Registrar, any Member whom he may consider eligible for the Fellowship; such Member, so named, taking his chance of election (to the Fellowship) by the *Fellows in Comitia* in the same way as, and in common with, those other Members duly nominated by the Council at "*those secret meetings*" concerning which "*there are such ugly rumours afloat.*" But the above "*mode*" is directly seen to be a mere apology for "*reform*"; a poor piece of expediency held up (as it is) for the acceptance and admiration of the readers of the *Journal of the British Medical Association*, the writer of which does not seem so free from the *nervous debility* and *hysteric tendencies* named by him, as to throw off those very much too active conservative tendencies, chaining him, as these evidently do, to the rude and misshapen past.[1]

This first mode of action, then, being untenable and out of harmony with the *day* and its requirements, we must pass it by.

2nd. The "*movement*" alluded to in your "Notes." This has much higher claims on our attention than the last specified

---

[1] See *British Medical Journal* for June 13, 1868.

It partakes of a far less exclusive principle, and hence does it recommend itself more or less favourably to the attention of all who would diminish by slow, yet certain, means the many and present signs of a medical oligarchy among us. The proposal "*for giving to the body of Fellows at large the opportunity*" of naming Members for promotion, shifts a good measure of power from the hands of the Council to the mass of the Fellows. *So far good.* But even then, and under such circumstances, should we not fail to hit the high mark—to be discerned in the future—and that future not so far distant? I think so.

3rd. The last mode of action—to which I would invite your attention—is that one which takes an especial cognizance of the MEMBERS themselves.

Now, in the *Lancet* for July 14, 1866, is a letter of my own, in which are these words, viz.:—"The best and only 'reform' competent to place the election of Fellows on a reasonable and just basis appears to me to be that one which involves a large addition to the present number of electors. When the College franchise is extended to its legitimate bounds, and embraces not only the Council and the Fellows outside it, but the less aristocratic MEMBERS themselves—then, not unlikely, will be brought within the narrowest limits possible all kinds of discontent and dissatisfaction. Moreover, if each Member of the College of Physicians had the privilege of recording a vote in the election of a FELLOW, would not the Fellowship be then more highly prized than it is?" It is added—"Probably the very few and faint reformers in the Pall-Mall camp may consider the admission of the *Members* within the pale of the College-constitution a dangerous and revolutionary innovation; others, again, in their admiration of a manhood suffrage, may be disposed to look with no small complaisance on such an extension of the representative principle as that indicated."

I would venture to say that, in so far as one can well judge, neither the many of the Fellows, nor the members, can hope for any really beneficial changes in the College of Physicians of London, if they fail to ask for and demand the same. To myself it is surprising to witness the apathy or indifference which has to this time marked the bulk of the members of the Royal College of Physicians (London). For instance, the publication of that famous, or rather infamous, bye-law in 1859, which declared that the "Registrar should not address *any* of its members with the title of DOCTOR, who did not possess a degree in medicine from some recognised university," was accepted with scarcely a sound word of either complaint or reproof. An effort made in 1862, by the insertion of an advertisement on the cover of the *Lancet*, to start some life into the insulted members of the College, met with no kind of response. It was not until a most one-sided and unjust comparison appeared in the columns of the *British Medical Journal* for May 7, 1864—as between the King and Queen's College of Physicians in Dublin, and the London College of Physicians—that the ways and the means were opened up, by myself, to be rid of "*the act of injustice*" inflicted on a large and important body of medical men. The result effected, though by single-handed endeavours, proved that my "*complete misapprehension of the facts of the case,*" and not less my "*unreasonableness*"[1] and ignorance existed but in the fancy of my very Conservative opponent. The recall of the said "act of injustice," and the full acknowledgment of the "*error,*"[2] prove as well the righteousness of my cause, as the defendence of everything like progress, in regard to the College of Physicians of London, on the many (Fellows and Members) to this time excluded from their rights and privileges.

One word more. It is much to be regretted that the very recently made batch of "Fellows" did not, "*estimating the Fellowship at its proper value*" (I mean, of course, its present, *not* its future value), respectfully decline the favours when offered to them, and prefer to remain simply *Members of the College.* Had such occurred, the effect would have been both marvellous and salutary, whilst each gentleman of the said "*batch*" would have gone far towards immortalizing himself, or something not unlike it.—Your faithful servant,

JAMES GEO. DAVEY, M.D.,
Member of the Royal College of Physicians of London, &c., President (provisional) of the Medico-Political Association of Great Britain and Ireland.

Northwoods, near Bristol, August, 1868.

Medical News.

OXFORD UNIVERSITY.—The *Times* says every possible publicity ought to be given to the fact that all the opportunities and privileges of the University of Oxford are now open upon payment of the entrance fee of £5, and the yearly payment of £3, 10s. Every town in the kingdom, it says, ought to have dozens of young men qualified to avail themselves of this most liberal offer.

THE Military Secretary, India Office, presents his compliments to the editor of THE MEDICAL PRESS AND CIRCULAR, and begs to enclose a list of the candidates for her Majesty's Indian medical service, who were successful at the competitive examination at Chelsea, in February, 1868, and who have undergone a course of instruction at the Army Medical School, together with the total number of marks obtained at the examinations at Chelsea and at Netley.—India Office, 28th August, 1868:—

	Name.	Studied at	Total No. of Marks.

MEDICAL OFFICERS OF HEALTH.—In addition to the towns mentioned in our last number as having appointed health officers, we may mention Sligo, for the Corporation of that town have secured the services of so earnest a sanitary reformer as Dr. Tucker.

THE ABYSSINIAN REWARDS.—Now, when the Abyssinian rewards have been distributed there seems to be some little chance of the achievements of the invading army being appraised at their proper value. The *Times* very properly calls attention to the omission of Colonel Merewether's name from the lucky catalogue, and also wonders how General Russell could have been left out in the cold. How is it that our influential contemporary has not also a good word to say for the medical officers, all mention of whose services was unaccountably left out in the first instance, although the whole expedition had been pronounced by competent authorities to be purely an engineers' and doctors' victory. Not until the strongest remonstrance had been published in the press was any attempt made to do justice to a body of officers to whose skill and attention is mainly due the gratifying fact that, in so far as sickness was concerned, the Abyssinian despatches included a clear bill of health. As to the men who first entered Magdala "methinks there be six Richmonds in the field," so many officers are successively putting in their claims to that distinction. We were led to believe that the two first men to enter Magdala were a bugler and a drummer of the 33rd Regiment, whose claims we never ceased putting forward, until at last they were rewarded with the Victoria Cross. However this may have been, the fact seems to be that Sir Stafford Northcote was, in the first instance, a little too exuberant in his gratitude, and that the officers who got home first reaped the field of reward bare. The Commander-in-Chief has been pretty well taken care of, as well as such officers as were fortunate enough to be honoured with his friendship. If it be true, as the *Times* says, that a distribution of the Star of India was intended, and that such distribution has been prevented by a rule of the order restricting it to services performed in India, it cannot be possible that deserving officers are to be put off with such a mere quibble. If there has been a mistake in this matter, it has been the mistake of her Majesty's Government, and her Majesty's officers must not suffer for it. The whole affair has its moral, which we long since sought to "point," at a time when we stood almost alone amongst the journals. Not very long since we had the Abyssinian Expedition lauded as one of the greatest of our military achievements, and now we find it sneered at by a great "public instructor" as a campaign in which the only "killed in action" were "two non-combatant mules."—*United Service Gazette.*

◆

NOTICES TO CORRESPONDENTS.

Mr. G. T. DOMVISTHORPE, Exeter, is thanked for his note and enclosure.

Mr. L. A.—Your application for reprints arrived after the type was distributed. When copies of any particular article or communication are required, it is absolutely necessary that the request should reach us not later than the Tuesday preceding each publication.

H. W. O.—The colour is somewhat against the general adoption of the article you mention in the preparation of milk foods for invalids; but from samples of the flour tested by us, we can add our testimony to the genuineness of the production.

BIRTH.

GELSTON.—August 25th, at 62, George-street, Limerick, the wife of Dr. Gelston of a son.

Advertisements.

THE LONDON SURGICAL HOME,

FOR Diseases and Accidents of Women; for the Reception of Gentlewomen and Females of respectability, upon a weekly payment, under the management of Mr. BAKER BROWN.

The Private Medical Attendants of the patients are invited to visit them, and to meet in consultation before treatment.

Full particulars can be obtained on application to the LADY SUPERINTENDENT, 18, Stanley-terrace, Notting-hill, London, W.

30th November, 1867.

LONDON NURSES' INSTITUTE,
118, New Bond-street, London, W.
(Removed from 42, SOUTH AUDLEY-STREET.)

TRAINED NURSES (Medical, Surgical, Mental, and Monthly), can at all times be obtained from this Institute.

Hospital Appointments by special arrangement.

Letters and Telegrams should convey the nature of the case to be attended.

Apply to the Manager or Matron. T. HAMILTON, Manager.

TO DISPENSARY OR WORKHOUSE MEDICAL OFFICERS.

A Highly Qualified Physician, Surgeon, and Midwifery Practitioner is anxious to obtain temporary employment as Locum Tenens for a short period. Address to A. B., Apothecary, Meath Hospital, Dublin.

IN consequence of the intended retirement of a medical gentleman from an old and valuable Practice, a peculiarly advantageous opportunity is afforded for a successor possessing first-rate qualifications.

Address M.D., MEDICAL PRESS AND CIRCULAR Office, 3, Lincoln-place, Dublin.

THE FRIENDS of a GENTLEMAN who is in good bodily health, but subject to delusions, are anxious to place him under the care of a Physician or Clergyman, where he would be treated in all regards as a member of the family. England would be preferred.

No proprietor of a lunatic establishment need apply.

Application to A. B., MEDICAL PRESS AND CIRCULAR Office, 3, Lincoln-place, Dublin.

ESTABLISHED 1848.
PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.
50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (KING'S COLL.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

MIDLAND—PARTNERSHIP.—There is an opening for a Junior Partner in an old-established Practice in a good town. The successor must be a Gentleman of superior education. Income £1400 a-year—capable of great increase. A Third Share to be negotiated upon the basis of two years' purchase. There is no dispensing, and the fees are good. Excellent residence; rent £50. Address X. 365, care of Mr. Langley, as above.

OPEN SURGERIES and RETAILS.—MR. LANGLEY has at present on his Books several eligible investments of this kind, at very moderate prices.

DURHAM.—For immediate Transfer, the Vendor having accepted an Appointment elsewhere, an old-established Practice, realising £500 a-year. Very moderate terms would be accepted, and a portion of the premium could be paid by instalments. Address X. 363, care of Mr. Langley, as above.

LONDON.—In a good suburb, a Partnership for Transfer. Present income upwards of £2000 a-year, and capable of still greater increase. The house is well situate; rent £100 a-year. Address X. 361, Mr. Langley, as above.

IN a pleasant country town, a Practice for Transfer. Receipts £450, appointments £260. House very convenient, with garden and stabling. A year's introduction given if required. Address X. 360, Mr. Langley, as above.

SOUTHERN COUNTIES.—For Transfer an old established Practice, in an improving district, within easy access of London. Receipts £1000 a-year; appointments £80. Population 2000, and only one opponent within three miles. House, with garden, stabling, &c., at a very moderate rent. As the vendor has the offer of a desirable appointment, a moderate premium would be accepted. Address X. 359, Mr. Langley, as above.

COMPETENT ASSISTANTS Provided without delay, free of expense to the principal. No gentleman recommended whose antecedents have not been inquired into. Apply to Mr. Langley as above.

LOCUM TENENS can be despatched by an early train after receipt of letter or telegram stating terms, duties, and qualifications required. Fee 10s. 6d. Address Mr. Langley as above.

Now ready. Second Edition, with considerable additions.

ADVICE on Buying or Selling Medical Practices, Partnerships, &c. By J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. Free by post for seven stamps, from the Author, 50, Lincoln's-Inn-Fields.

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION: THEIR DIAGNOSIS AND TREATMENT.

BY S. SCOTT ALISON, M.D. EDIN.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

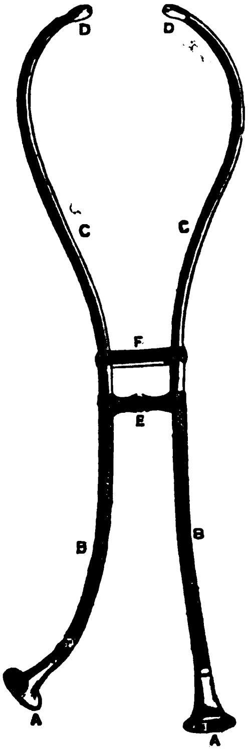
No. VI.

FOR stethoscopic purposes, the neck may be divided into regions after the following simple manner—viz., an anterior region and a posterior region. One line for the anterior region is drawn from the middle of the hyoid bone to the middle of the upper edge of the sternum. A line drawn from the mastoid process of the temporal bone passing down the neck to the acromion process forms the posterior boundary, and separates the anterior from the posterior region. The posterior region is bounded behind by the spines of the cervical vertebræ. These two great divisions of the neck may be again subdivided into superior and inferior by a line drawn round the neck from the cricoid cartilage of the larynx to the spinous process of the fourth cervical vertebra.

The superior anterior cervical region would include the glottis and the larynx, and might be called the laryngeal region, while the inferior cervical region would include the trachea and the narrows immediately above the bifurcation. The superior posterior cervical region extending from the occiput to the spine of the fourth cervical vertebra would include the pharynx, the posterior nares and the posterior aspect of the tonsils.

The auscultation of the throat may be effected with the ordinary wooden stethoscope, but the flexible stethoscope of Caman, or the differential stethoscope of the writer, is greatly preferable. The air sounds of the throat are well made out with Caman's instrument; the sounds are well collected by the cup without undue pressure upon the comparatively tender and yielding neck, and they are distinctly perceived by the two ears being employed upon them. The same advantages are procured by the differential stethoscope, but the additional advantage of very ready location of the seat of disease appertains to the latter by its possessing two sound-collecting cups, placed at different spots of the neck, and connected with the two ears respectively.

The absence of pressure on the neck, which the flexible stethoscopes afford, gives them a very great superiority over the ordinary wooden stethoscope; and if we regard this fact, and also bear in mind, in the case of children, the advantage we enjoy with these instruments, of sitting in front of the patients and almost of amusing them, we shall come to the conclusion that any examination of the throat must be imperfect and incomplete without one or other of them.



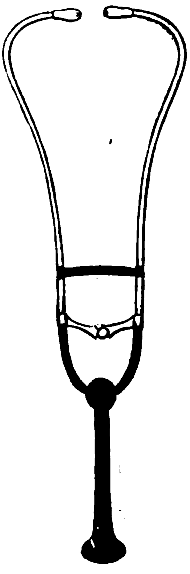
Scott Alison's Differential Stethoscope.

The differential stethoscope has two tubes—one for each ear—and instead of communicating with one collecting cup only, as in the case of the double (Caman's) stethoscope, they have each a separate cup A A. It presents a separate stethoscope for each ear. These are mechanically combined for facility of management, but they are in an acoustic sense totally separate. The tubes are partly made of metal, C C, and partly of elastic tube, B B, to admit of some degree of motion. The two tubes are connected together, as in Caman's stethoscope, by a jointed metal bar, E, and an india-rubber band, F. There are two ear knobs, D D, of ivory for insertion into the two ears respectively.

The principle of Caman's instrument, and indeed of any other double stethoscope, is very different from that of the differential stethoscope. The double stethoscope enables us to hear the sound of the same part with both ears,—virtually to place both ears upon one part of the chest, and thus receive a simply heightened sensation. The differential stethoscope enables us to do more than this; we hear, or deal with the sounds of two parts at the same moment, and virtually place our two ears upon two different parts of the chest at the same instant. While the double stethoscope of Caman, having only one sound collector, cannot be converted into a differential stethoscope, by collecting sounds from two parts of the chest at once, the differential stethoscope may be made simply a double stethoscope by placing its two sound-collecting cups upon the same part of the chest. The property which my differential stethoscope possesses of eclipsing a minor auditory impression in one ear, upon conveying a major amount of the same sound into the other ear, is of very great value in practice. When the respiration or vocal sound in one part of the throat or chest is weaker than in another part, this is signified in an unmistakable manner by the sound being heard in that ear, and in that ear only, connected with that part of the body emitting the larger amount of sound. One ear monopolises the sensation, as it were, and the other is deprived of all sensation, as it were; for we seem to hear only through one ear—viz., the more favoured one.

It was from observing the utility of Caman's stethoscope, as used by Dr. J. Edward Pollock, in 1856, at the Brompton Hospital, that I was led to think of the differential one. As was before mentioned the mechanism is much the same, but in point of acoustic results the two instruments are very different, as I have more fully explained in my work on the "Physical Examination of the Chest in Pulmonary Consumption," published in 1861.

It may be useful to say, and it is done from no feeling of vanity or undue partiality that, the differential stethoscope is used in many distant parts of the globe, and that, some of the first stethoscopists in the world have been the most earnest in its recommendation. Gairdner, of Glasgow; Hughes Bennet, of Edinburgh; Bree, of Colchester; M'Kinnon, of Netley Hospital; and Frank, of Mentone, were among the first to appreciate the value of the differential stethoscope.



Caman's Double Stethoscope.

These flexible instruments are so specially suited for the auscultation of the neck, and to such an extent, as to seem to me to justify this short account of them in this communication.

The laryngoscope hitherto has purposely been left unnoticed in this paper, for it has been a primary consideration with me to enforce the propriety of auscultating the neck, and indeed of regarding that region as only second to the chest in its call for the employment of the stethoscope. In all cases of simulated consumption, combined with throat symptoms, it is incumbent upon the practitioner to employ the laryngoscope and obtain for his guidance in the relief of the patient the benefit of ocular inspection. On the mode of employing this instrument, or series of instruments, it is not my intention here to dilate. So much has been written on the subject, both abroad and in this country, that the reader can be at no loss for information.

The writings of Gibb, Morell MacKenzie, George Johnson, and Prosser James, are, perhaps, the most worthy of the attention of the English practitioner.

CANNABIS INDICUS IN CATARRHUS SENILIS—VERATRUM VIRIDE IN PERICARDITIS—BELLADONNA IN INFANTILE ICTERUS.

By J. WARING-CURRAN, L.K.Q.C.P.I., &c.

In the July number of the *Practitioner* I briefly directed attention to the invaluable and important nature of cannabis indicus in catarrhus senilis as a therapeutic agent. Since the publication of that journal I have had additional opportunities afforded me of still further testing the efficacy of the drug in this distressing complaint, and of verifying the statements I then made. I refer to those cases of senile catarrh where the mucus accumulates in the bronchiæ, which the patient is unable to expel, where the constant, dry, hacking cough affords no relief to the pent-up mucus; while it harrasses the patient, and increases the prostration where there is orthopnea; and unless the distressing symptoms are quickly relieved by remedies which will cause or promote a free and copious expectoration, blue blood will quickly circulate through the brain, the lungs become congested, and a fatal termination occur to the patient sooner than was anticipated or expected by either the attendant or relatives. Cases, owing to their repeated occurrence, over which the usual antispasmodic mixtures, expectorant pills, opiates, and counter-irritants seem to have lost their influence and power, yet in which cannabis appears to act speedily and satisfactorily—speedily by its specific action in overcoming the spasm of the muscular fibre in the bronchial tubes, and thus allowing a free and copious expectoration; satisfactorily in its consequences, as it possesses none of the disadvantages of opium and medicines of its class, in blocking up the secretions, increasing the fever attendant upon the complaint, producing headache and impairing the appetite; in fine, when administered in such affections, its effects are to be witnessed rather than described.

Case 1.—R. S., aged 57 years, of delicate appearance, with narrow shoulders and contracted chest, has suffered from repeated attacks of chronic bronchitis, of which she states the present is the worst attack of all. Has been ill four days. The usual domestic nostrum, paregoric, linseed tea, and Spanish juice, *et hoc genus omne*, have lost their virtue, and failed to afford relief.

The skin over the anterior part of the chest is well blistered, owing to the repeated applications of mustard poultices. The secretions are normal, and the bowels have received attention. The patient has been unable to lie on the back since the commencement of her illness, depending on the constant and distressing nature of the dyspnœa.

On stethoscopic examination all sorts of sounds are audible, on both inspiration and expiration; sibilant rales are most distinct at the base and rhonchi at the superior part of thorax. There is a constant, dry, protracted cough, which "cannot get round," to use her own words, "the obstruction."

The pulse is 120; the skin moist; the lips livid, and the face blanched and indicative of suffering.

℞ Tr. Cannabis indicis ʒii.
Pulv. Tragacanth co. ʒi.
Ether chloric ʒiss.
Aquæ anisi ad ℥vj.
Fiat mist., et capiat ʒi. 2ndis horis.

The following day, I learned before three doses of the mixture was taken, the cough became "loose, and the expectoration easy and most profuse." She expectorated freely for several days, and rapidly recruited on a liberal regimen, and bark and ammonia mixture.

Case 2.—A. B., aged 69, subject to frequent bronchitic attacks, has been ill for a week, expectorates but little, and with considerable difficulty; is very feeble, and has been taking ammonia and senega with little alleviation, ordered the Tr. cannabis in mixture, which produced the desirable effect of liberating the mucus and affording relief to the cough. Speedy recovery.

Case 3.—R. P., 70 years of age, has been previously under treatment for catarrh, now presents all the unequivocal symptoms of chronic catarrh. Has recovered sooner under the effects of cannabis than from any of her previous attacks; has grown fond of her medicine, which produces free expectoration after the administration of each dose.

Case 4.—J. P., aged 60, speedily and satisfactorily recovered from a severe and protracted attack of catarrhus senilis after the exhibition of cannabis indicis.

VERATRUM VIRIDE IN PERICARDITIS.

The August number of the *Practitioner* contains a condensed paper of mine on the important therapeutic effect which I have obtained from the administration of veratrum viride in pericarditis. I believe it to be preferable to opium, which hitherto has been our sheet-anchor in this disease, when combined with calomel, because of its magical influence in overcoming that irritable condition of heart, so pathognomonic of the malady; by its certain power, if carefully watched in its administration, of reducing the frequency of the pulse, thereby affording relief to the violent palpitation and tumultuous action of the heart, giving steadiness to the hitherto irregular pulse, quieting the respiration, alleviating the darting pains so characteristic of the complaint, and enabling the patient to swallow with less difficulty, and change his position in bed as it becomes painful, while it increases to a marked degree the renal and hepatic secretions, of no little moment in such a disease as pericarditis.

I invariably employ the extract—considering it the safest and surest preparation—made by inspissating the juice of the root, and prescribe it in two grain doses, with one grain of calomel in the form of pill, every two hours until its effects are readily discernible. The distressing symptoms are then kept at bay until the calomel does its duty, and the disease mastered. Advocates for local or, perhaps, general depletion, have only to observe its therapeutic influence once, to feel convinced that we *do* possess a remedy which will afford all the benefits to be obtained from either bleeding, leeching, or cupping, without impoverizing the blood and increasing the tendency to serous effusion, constituting *hydrops pericardii*, which has been unfortunately not an unfrequent consequence of this disease, particularly in hospital practice.

The history of the three following cases will impart all that I would fain convey on the subject:—

Case A.—R. R., aged 27 years, the subject of rheumatic fever, for which he has been under treatment six days; on the seventh day of his illness he presented all the well-marked symptoms of pericarditis. On going into the room I noticed that peculiar distressed, broken-hearted appearance of face so indicative of cardiac mischief; there was visible pulsation of carotids, hurried respiration, tumultuous action of heart, and *decubitus* on right side. He complained of severe lancinating pain extending up between the shoulderblades to the left side of neck, thence extending down the arm of same side; pulse 130; respirations 40; skin dry; tongue parched; secretion arrested; high fever. On practising auscultation, a well-marked *to-and-fro* sound is audible, all the unequivocal symptoms of acute pericarditis being present. I immediately put him on two grains of the extract of veratrum viride, and one grain of calomel, to be given in pill every two hours, with a potass mixture, and a mustard blister to be applied over the cardiac region.

Evening Visit.—Pulse 60; respiration 20; bowels have been operated on twice, bilious, feculent stools; passed a large quantity of acid urine; more free from pain, and expresses himself easier.

Owing to vomiting, which set in later in the night, I discontinued the veratrum, and prescribed an effervescing mixture containing dilute hydrocyanic acid.

The following day there was an aggravation of the symptoms—the veratrum was renewed, and steadily employed, discontinuing it when the symptoms required me, until a complete and satisfactory cure was effected. The patient recovered without a bad symptom, and is now attending to his usual avocation.

Case B.—This was also a well-marked case of rheumatic pericarditis, presenting all the symptoms of the complication to a marked degree. The veratrum brought down the pulse from 120 to 70 in the course of twenty-four hours, increased the secretions, and produced a most desirable termination.

Case C.—Pericarditis with severe dyspnœa and violent nter-scapular pain; irregular pulsation and congestive tendency. The veratrum produced its usual effects, and, combined with the calomel, in a few hours alleviated the suffering of the patient, increased the secretions, and relieved the pulmonic circulation. The patient is now as well as ever he was.

In three cases of acute rheumatism, in which pericardial symptoms threatened, although did not positively manifest themselves, I feel assured that the mischief was baffled by the early and careful exhibition of ten-drop doses of the tincture of veratrum viride in the athritic mixture.

BELLADONNA IN INFANTILE ICTERUS.

Sir Thomas Watson, in his elaborate work on the "Practice of Medicine," states that he believes *icterus neonatorum* is not icterus at all, and has no relation to the biliary organs, but that the child at the time of its birth being in a hyperæmic or congested condition, presenting an universally bruised appearance, which gradually fading gives, as the redness disappears, shades of yellow, which in a day or two pass, or are converted into the genuine flesh colour. This is all very nice in theory, but in practice, when one meets with an infant jaundiced over the surface of the body universally, the conjunctiva tinged, abdominal disturbance indicated by constant symptoms of pain, incessant crying, pressing the legs spasmodically against the abdomen, general muscular twitchings, vomiting, and discoloured and fœtid evacuations, one does not feel inclined to wait for the yellow tinge to pass into the normal flesh colour.

Having paid considerable attention myself to the subject, I have found that infantile icterus is of very frequent occurrence, and in many cases requires prompt remedying. In several instances which lately came under my notice the symptoms were very severe, painful to witness, and disturbing to the entire household.

I am of opinion that the bile in these cases is not *suppressed* in its secretion, but that it is *retained*, that the liver and gall bladder become surcharged and distended, that little, if any, bile passes through the *ductus communis choledochus*, and have reason to think that the mischief lies either in the duodenum or common bile-duct, that a spasmodic condition of these parts, from the irritation or passage of the bile through the delicate structures, is the cause of the mischief. The duct becomes spasmodically closed, the bile, instead of being eliminated as it is secreted, is blocked up in the liver, and we have re-absorption of it taking place into the blood.

A few months ago I had the opportunity of making a post-mortem examination of a child aged seven days, who died from an injury to the head produced by falling from the nurse's arms. It had been previously out of health, and from the generally tinged condition of the skin, I was induced to examine the liver. I found it preternaturally enlarged, distended with bile, and in carefully examining the duodenum and common bile-duct, I found the duct narrowed, and the characteristic tinge made by fresh bile entirely absent. I came then and there to the conclusion, that the duct had been spasmodically closed during life, and thus the egress of the bile prevented.

That I have been correct in my opinion is best exemplified by the immediate relief afforded in the treatment of similar cases by tincture of belladonna in two-drop doses. After its administration, there is an end to the incessant crying, the child falls asleep, passes bile freely by the bowels, and rapidly recovers its natural state and condition. The administration of calomel I consider unnecessary and cruel. The act of secretion has gone on naturally enough. The elimination of the bile is what is required, and for this purpose tincture of belladonna will be found expeditious and curative, by overcoming the spasmodic condition of that portion of biliary apparatus so frequently affected in children a few days after birth.

AMPUTATION OF THE PENIS FOR CANCER: RECOVERY.

By HENRY GRAY CROLY, F.R.C.S.I.,

SURGEON TO THE CITY OF DUBLIN HOSPITAL, ETC.

Mr. ———, aged 65 years, was brought to me by his medical attendant to have the penis amputated for cancer.

History.—Had congenital phymosis. Six months before consulting me he felt a hard and tender spot on the inside of the prepuce at the left side: he thought it was produced by the saddle, as he was in the habit of riding long distances on horseback. He never suffered from venereal disease in any form. The hardness in the prepuce extended to the glans penis, which soon became entirely involved in the disease. The patient suffered intense pain of a burning, lancinating character, and was obliged to take large opiates to produce temporary relief. His prepuce was slit up by his medical attendant a few days before I saw him.

Appearance of patient and diseased part before operation.—General health excellent. Arcus senilis well-marked. Heart's sounds strong and natural. Penis enlarged. Fœtid discharge of sanious fluid from beneath the prepuce. On examining the glans it feels as hard as a stone. The hardness extends to within one inch and a half of the pubes. No glands enlarged in the groin or on the dorsum of the penis.

The patient was most anxious for immediate operation, which I accordingly performed at his residence, assisted by his surgeon. Chloroform having been administered, I grasped the penis and drew it gently forwards. With one sweep of the catlin the organ was severed behind the diseased part. The dorsal arteries and those of the corpora cavernosa were ligatured, and a small branch close to the urethra. When all hæmorrhage was controlled I passed a scissors into the urethra, and divided it fully half-an-inch. The angles of the divided mucous membrane were then stitched to the integument at each side. A No. 8 gum-elastic catheter was introduced into the bladder, and retained. The ligatures came away within a week, the wound healed, and the patient made an excellent recovery.

Microscopic examination showed the disease to have been epithelial cancer.

I devised a silver funnel to fit over the pubes, which enables the gentleman to pass water without wetting his clothes, thereby contributing much to his personal comfort. The appliance was manufactured by Weiss, of London, by direction of Fannin and Co., Grafton-street, Dublin.

Remarks.—Diagnosis of cancer of the penis must be carefully made, especially if the disease occurs at or before the middle period of life, when syphilis is more likely to exist than in advanced life. Congenital phymosis is a cause of cancer (according to Hey), the preputial discharge being retained producing irritation. In operating, the penis should not be drawn too much forwards, as retraction of the skin is liable to occur, thereby leaving the stump exposed. All bleeding vessels must be secured by ligature or acupressure; torsion is not suitable for vessels of the corpora cavernosa—secondary hæmorrhage is to be apprehended, and pyæmia has followed the operation. Removal of the penis by the ecraseur, if effected slowly, to prevent hæmorrhage, prolongs the operation unnecessarily. Free division of the urethra is of much importance, to avoid stricture at the orifice; and retaining a catheter in the bladder, for the first forty-eight hours, prevents irritation from the urine on the freshly-cut surface.

A CASE OF ILEUS SUCCESSFULLY TREATED BY ELECTRICITY.

UNDER THE CARE OF T. A. VESEY, A.B., M.B. T.C.D.

On July 14, 1868, I was called to see John Hughes, aged 59, a pensioner. Always healthy. Three months since was treated for enteralgia; subject to constipation. On the 12th, his bowels not being moved for two days, he took a dose of castor oil, followed by senna and salts, without effect.

Present Symptoms.—Spasmodic pain, starting from a hard moveable mass to the right of the umbilical region; pressure here caused increased pain; belly tympanitic; lineæ transversæ deeply marked; face pale, anxious; eyes sunken, dull; skin cool, clammy; feet and hands cold; tongue coated; vomiting (not stercoraceous) set in same morning; constant loud gurgling in bowels; pulse 94, fair volume.

Treatment.—A sinapism, followed by turpentine stupes, an emollient enema (3 pints) was given by a long tube, and retained one hour; came away unchanged; turpentine enema twice administered without carrying away any fæcal matter. Subsequently a 3 pint enema of warm oil (Dr. Head, Carlisle) brought away a trace of fæces.

No purgatives by the mouth; belladonna and opium in full doses with relief to pain, spasms, and vomiting.

15th.—Passed a tolerable night; had some sleep; pain less; abdomen becoming tender; pulse 104; vomiting very troublesome since 4 A.M.

Finding that the measures adopted for his relief did not produce any good effect, I determined to use electricity, applied as follows:—

Patient being placed on the left side, a "Radford's Uterine Director" was introduced into the rectum, and the negative wire of the electric machine attached to it. The sponge attached to the positive pole was rapidly passed over the whole abdomen from cœcum to left iliac region. This caused intolerable agony, as all the abdominal muscles were thrown into violent action. The electricity was applied (at intervals) with gradually increased power for half-an-hour, when such exhaustion was produced that it was discontinued.

As he complained much of pain in the back, a vulcanite hot-water bag was applied to it with relief.

In two hours after the use of the electricity, he had several copious, dark-coloured, offensive stools. During the rest of the day and night following, his bowels were moved twelve times. The pain disappeared, the hard mass was so much reduced as to be made out with difficulty. He made a rapid convalescence.

The failure of the ordinary measures in this case induced me to try the effect of electricity, and the successful issue furnishes additional evidence of the great therapeutical value of electricity in the treatment of ileus.

In the ninety-sixth number of the *Dublin Quarterly Journal of Medical Science*, will be found a case reported by Dr. Finney, in which electricity was used on Dr. Stokes' recommendation. It was the recollection of that case, and the favourable result, that gave me confidence in the trial of a similar remedy, and happily with similar good fortune. The battery used was a Davis and Kidder's electro-magnetic machine.

Hospital Reports.

RICHMOND SURGICAL HOSPITAL.

CASES UNDER THE CARE OF MR. WILLIAM STOKES.

(Reported by Mr. J. A. Ross, L.R.C.S.I.)

URETHRAL STRICTURE.

The results of the treatment by internal urothrotomy of the following cases of urethral stricture, tend considerably to confirm Mr. Stokes in the high opinion he has formed of the operation for the cure of this affection.

Case 1.—STRICTURE OF THE URETHRA OF THIRTEEN YEARS' DURATION, PREVIOUSLY TREATED TWICE BY THE "IMMEDIATE DILATATION" METHOD: INTERNAL UROTHROTOMY.

Michael B., æt. 43, was admitted into the Richmond Hospital, under Mr. Stokes' care, on the 22nd of last May, suffering from a very tight stricture of the urethra, situated in the region of the bulb, and which, with great difficulty, would admit No. 1 catheter.

The patient stated that in 1865 he had been treated by the "immediate method," and that the stricture having returned, the operation was performed a second time, by another surgeon, in July, 1867. The stricture had a second time recurred, and the difficulty in passing water was considerably greater than it had ever been.

On May the 23rd the operation of internal urothrotomy was performed by Mr. Stokes, and immediately after a No. 10 gum-elastic catheter was introduced.

No rigor or other evidence of any constitutional disturbance occurred during the patient's convalescence.

On the 27th the patient left hospital.

On September 3rd No. 9 catheter was introduced without the slightest difficulty.

The patient has been perfectly well ever since the operation.

Case 2.—STRICTURE OF THE URETHRA OF TEN YEARS' DURATION: INTERNAL UROTHROTOMY: RECOVERY.

Cornelius M., æt. 32, was admitted into the Richmond Hospital on the 10th of last March. The case presented all the symptoms of urethral stricture, which the patient attributed to gonorrhœa, and which the patient stated he contracted about eleven years previously. The stricture, situated in the membranous portion of the urethra, was so close a one, that it was not until after repeated trials that a No. 2 catheter could be passed. When this was done, Mr. Stokes then passed in the filiform bougie of the urethrotome, and completed the operation then, in the ordinary manner. A large gum-elastic instrument was immediately introduced after the operation.

Nothing untoward occurred during the convalescence of the patient, and more than four months after the operation No. 9 catheter could be introduced with the greatest facility.

Case 3.—STRICTURE OF THE URETHRA OF TWO YEARS' DURATION: INTERNAL UROTHROTOMY: RECOVERY.

Peter S., æt. 22, was admitted into the Richmond Hospital under Mr. Stokes' care, on the 20th of last March, suffering from stricture of the urethra, which he had, he stated, for the last two years. He attributed it to an attack of gonorrhœa, which had been treated by injections, and which he did not believe had ever been quite cured.

Mr. Stokes treated the case for some days by partially dilating the stricture by wax bougies, as the ordinary small sized gum-elastic catheter could not be introduced. As soon as the filiform bougie of the urethrotome could be passed, the remaining steps of the operation were completed in the ordinary manner. After the operation No. 10 gum-elastic catheter was introduced.

Four hours after the operation the patient had a rigor, but no other evidence of any constitutional disturbance supervened during the convalescence of the patient. A week after the operation, he left hospital able to pass water in a full and uninterrupted stream.

Case 4.—STRICTURE OF THE URETHRA OF FOUR YEARS' DURATION: INTERNAL UROTHROTOMY: RECOVERY.

Peter G., æt. 45, was admitted into the Richmond Hospital under Mr. Stokes' care on the 6th of last April. The stricture, situated in the membranous portion of the urethra was of four years' standing. The patient stated he never had any gonorrhœa, nor had he ever received any injury to the perineum. There was some obscurity therefore as to the cause of the stricture. The gradual dilatation method had been tried only, however, for the stricture to return afterwards in a still more contracted state. The stricture was situated in the membranous portion of the urethra. At the time of the operation No. 2 gum-elastic catheter could alone be introduced, and that with much difficulty, and requiring very delicate manipulation. The operation was performed in a similar manner as in the preceding cases, and immediately after No. 9 gum-elastic catheter was introduced. There were no rigors after the operation. Twenty-four hours after the operation, the instrument was withdrawn, and no instrument re-introduced for four days. No. 10 catheter was then passed without any difficulty. The patient then left hospital.

The first of these cases, operated on on the 23rd May, Mr. Stokes had an opportunity recently of examining. No. 9 catheter was introduced without any difficulty.

Cases 2 and 4 have also been recently seen and examined, and the condition of these two patients was found most satisfactory. Case 3 has not been seen since the operation, the patient having neglected to return to hospital for examination as he was directed.

The following points are of some practical importance:—

1. The operation should not be performed unless the grooved metallic director can be introduced *with facility*. Any forcing of this portion of the instrument into the bladder will, in the great majority of cases, be followed by rigors and other symptoms of constitutional disturbance.
2. The patient's bowels should be cleared by an enema on the morning of the operation.
3. Immediately after the operation a full opiate with quinine should be given.
4. The catheter introduced after the operation should not be allowed to remain longer than twenty-four hours. If it is, it will probably give rise to irritation, and the formation of an abscess where the stricture is divided.
5. No instrument should be re-introduced for at least three days.
6. The patient should be kept on milk diet for forty-eight hours after the operation, and no stimulants given.

DR. STEEVENS' HOSPITAL.

CLINICAL REPORTS

BY EDWARD HAMILTON, F.R.C.S.I.

FRACTURE OF THE CLAVICLE CAUSED BY MUSCULAR ACTION.

THIS bone, so frequently fractured by indirect violence, is rarely broken by muscular action, and yet cases now and then present themselves, which place the possibility of the occurrence beyond doubt. Various muscular acts have been recorded as resulting in fracture of the clavicle—*e.g.*, securing a carriage trace, mounting a horse, whipping a dog, shaking a wet coat. The following case illustrates this accident:—

J. H., a cabinet-maker, aged 48, a healthy man, fairly developed, presented himself at the hospital with all the symptoms and evidences of a fracture of the clavicle of the *right side*, a little external to the centre. He stated that a week previously he was pulling the lath from the hem of a linen blind, which, after considerable resistance, suddenly gave way; he felt something crack in his shoulder, with great pain and loss of motion in the limb; he did not mind it subsequently, but finding that the limb was still weak, he applied for relief. The fracture appeared to be quite transverse, and there was no difficulty in procuring perfect union. There was no history of syphilis, or other constitutional disease, to cause structural change in the osseous tissues.

POLYPUS OF THE RECTUM.

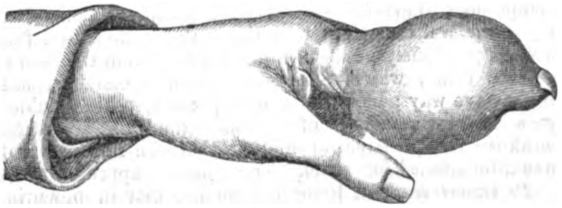
E. D., 12 years of age, presented himself as an outpatient; he had suffered for the last four or five years from tenesmus and constant hæmorrhage from the rectum; his aspect was pale and delicate, which his mother attributed to loss of blood: these symptoms at this early age suggested the idea of polypus—he was accordingly placed on his hands and knees, and directed to force down, when a polypus was protruded about the size of a filbert, very red and vascular; a wine ecraseur was applied to the neck of the tumour, and while it was being tightened the growth was drawn down, exhibiting a neck of fully an inch in length, attached to the posterior wall of the gut; steady traction was made on it, while a silk ligature was slipped round the pedicle, below which it was divided with a scissors. The age of the patient and the long narrow penduncle at once served to distinguish it from a pile, although the colour, the appearance of the surface, and the bleeding, might easily lead the superficial observer to an erroneous idea of its pathology.

TRAUMATIC ENCHONDROMA OF THE FINGER.

A. B., aged sixty, ten years ago received a severe blow on the index-finger of the left hand by the falling of a plank. The pain at the time was not very severe, but the finger remained sore and swollen, and gradually increased in size until about three years since, when it began to increase more rapidly, and was also more painful. On examination, the finger was considerably enlarged—about the size of a hen's egg,—had a peculiar elastic feel, amounting in parts to a sense of fluctuation; it felt hot and throbbing, and was very painful, but the pain was removed by gradual and steady pressure. The disease was limited to the finger; the metacarpo-phalangeal joint was perfect; there was no trace of glandular contamination; no evidence of cachexia. In every respect the case was favourable for operation, which was suggested to the patient twelve months before, but he was afraid to encounter it. The amputation was performed in the ordinary way. The end of the metacarpal bone was removed, as his occupation did not require the breadth of surface in the palm of the hand. Two vessels spouted during the operation, but ceased to bleed almost immediately, so that they did not require hæmostatic treatment. The wound was closed by means of sticking-plaster, one stitch only being inserted into the lower part of the wound. Silk steeped in carbolic oil was used for the purpose. The parts were covered with the antiseptic putty and tinfoil, and the bandages well soaked in the oil. The dressings were not disturbed until the fifth day, but were each day saturated with the oil, a little matter appeared under the edge of the bandages, but the entire suppuration did not amount to half an ounce.

On making a section of the tumour it presented all the characters of enchondroma, which were corroborated by the microscope. It had grown from the second phalanx, which was completely merged in the tumour, and from thence extended up on each side of, but did not implicate, the first phalanx. The digital nerves on each side were much enlarged and flattened, which may explain the increase of pain.

Altogether, the disease was a fine specimen of traumatic enchondroma :—



ANEURISM OF AORTA.

W. M., a plasterer, æt. 29, was brought under my notice through the kindness of Dr. Shortt. He presented a well-marked tumour of right lumbar region, projecting between the last rib and the crest of the ilium. Also, somewhat in front, it exhibited distinct diastolic impulse, and bruit de soufflet audible in front, but not behind. His general appearance was anæmic and unhealthy, and he suffered severe pains of a neuralgic character in the *back*, groin, and knee; he stated that he was in perfect health, and worked hard at his trade until six months ago, when he became affected with pains, which he attributed to rheumatism. He did not observe any enlargement of the side until three weeks before. He was admitted to hospital, and underwent a careful physical examination, from which was deduced the diagnosis of an aneurism of the aorta behind the cœleac axis, becoming diffused toward the right side. The tumour rapidly enlarged, attended with the most agonising pain and loss of sleep, which was with difficulty procured by the strongest anodynes. The tumour became somewhat dark on its posterior surface, and after a few days the extremities became cold, and he gradually became weaker and weaker. The post-mortem examination revealed an enormous mass of blood occupying the right side of the abdomen, behind the peritonæum, extending up behind the liver to the diaphragm, and down in the substance of the psoas muscle, which encapsuled it to Poupart's ligament. Immediately behind the mouth of the cœleac axis and superior mesenteric artery a large aneurism existed, eroding the vertebra. It became diffused behind the liver and kidney, both of which organs were projected forward.

KING'S COLLEGE HOSPITAL.

CASES UNDER THE CARE OF DR. BEALE, F.R.S.

(From brief notes by Dr. TONGE.)

DYSPEPSIA.—G. A., æt. 36, gardener. Admitted March 8; discharged March 26. In hospital 18 days. *Recovery.* Five weeks ago while straining at work sudden pain in loins, epigastrium, and right hypochondrium, continuing up to present time. Loss of flesh and strength, disturbed sleep, sour risings, occasional retching, pain aggravated by food.

Mist. rhei. co. iodide of potassium, bicarbonate of potass. and chloric ether; castor oil and opium; linseed and laudanum poultice.

DYSPEPSIA.—Mary A. C., æt. 19, servant. Admitted December 18; discharged February 13. In hospital 57 days. *Recovery.* Slight hæmoptysis six months ago; loss of flesh six months; epigastric and dorsal pain after food; sour risings.

Mist. rhei. co.; bismuth, magnesia, soda, calumba, and hydrocyanic acid; pepsine and hydrochloric acid; quinine, sulphate of iron, and sulphate of magnesia.

DYSPEPSIA.—Cornelius K., æt. 38, street fruit seller. Admitted December 1; discharged December 20. In hospital 19 days. *Relieved.* Abdominal pain and vomiting 14 days; bowels confined for one week before; much tenderness at a spot two inches above umbilicus; tongue furred.

Hydrocyanic acid and carbonate of soda; pepsine and hydrochloric acid; grey powder, rhubarb and henbane.

DYSPEPSIA.—Mary A. P., æt. 40, married. Admitted February 2; discharged February 20. In hospital 18 days. *Relieved.* Catamenia ceased two years ago; pain in right side 18 months, constant last three months; tremor of right leg and arm 18 months; hæmatemesis 10 weeks ago; loss of flesh and colour of late. On admission pain in right side; small deep-seated moveable tumour in epigastrium; occasional vomiting; appetite bad; tongue furred; bowels confined; right leg dragged slightly in walking.

Pepsine and hydrochloric acid; effervescing mixture; quinine and sulphuric acid; purgatives; hydrochloric acid lotion.

HYDATID (?) TUMOUR OF LIVER.—Mary A. M., æt. 22, widow. Admitted July 1; discharged August 3. In hospital 33 days. *Relieved.* Occupation sedentary; had acute rheumatism six years ago; since then a tumour to right of epigastrium only occasionally painful up to one month ago, since then constantly so; never jaundiced; no loss of flesh. On admission tumour 3½ inches transversely, nodulated (?), extending two inches below costal margin to edge of liver, felt in same situation and descending with liver on inspiration; appetite good; tongue clean; pain and tenderness became much less while she was in hospital.

Liq. ammon. acetatis and aromatic spts. of ammonia; belladonna plaster.

Re-admitted October 1; discharged November 9. In hospital 39 days. *Unrelieved.* Since discharge the tumour has become larger and more tender, but there has been no loss of flesh. The tumour got slightly larger and more painful while she was in hospital.

Quinine and dilute sulphuric acid.

Colic.—W. P., æt. 23, a blacksmith. Admitted May 26; discharged May 30. In hospital 4 days. *Recovery.* Slight epigastric pain and purging 6 days; much vomiting and intense abdominal pain on day before admission; scybala brought away by injection. Then slight jaundice.

Castor oil and warm water enema. Aromatic spts. of ammonia and sulphate of magnesia.

Colic.—R. B., æt. 50, smith. Admitted July 14; discharged July 16. In hospital 2 days. *Recovery.* On morning of admission ate some tainted meat, and, a few minutes afterwards, was seized with severe abdominal pain, vomiting, and purging, followed by faintness.

Warm bath. Aromatic spts. of ammonia and chloric ether.

Abscess of Liver.—W. R., æt. 22, sailor. Admitted December 2, 1863; discharged March 23, 1864. In hospital 112 days. *Unrelieved.* Left West Indies two years ago; soon afterwards jaundice 7 weeks, followed by loss of strength; pain and enlargement of liver 6 months; diarrhœa for 1 month, 4 months ago. On admission, skin dark, slightly jaundiced; pain and tenderness on pressure in right hypochondrium and epigastrium; pain sometimes in right shoulder; liver from sixth rib to below umbilicus; slight dulness and faint tubular bruit over base of right lung; motions dark; frequent paroxysms of severe pain in liver; diarrhœa after 30th day from admission. Forty days later, expectoration of pus streaked with blood; dulness and crepitation at left apex. Slight hæmatemesis 35 days later.

Chloric ether and iron (first sesquichloride, then citrate). Nightly opiates. Hydrochloric acid lotion over liver.

Re-admitted April 5. *Died* on May 20. In hospital 45 days. Pain in liver has increased since discharge; right side now extremely tender. Eighteen days later began to expectorate viscid, brownish-red sputum; two days later, pain worse; much dulness and crepitation at right base; some dulness at left base; nineteen days later, purged five or six times daily; expectoration abundant, fœtid, yellowish-brown; orthopnœa; exhaustion; death.

Post-mortem.—Liver fatty and much enlarged, extending to one inch above umbilicus; the upper two-thirds of right lobe occupied by an abscess, lined by a cyst one-fourth of an inch thick, containing stinking pea-soup coloured pus, its anterior surface adherent to the abdominal wall; base of lower lobe of right lung yellow and disintegrated, and communicating with abscess by an aperture in diaphragm, which was adherent around it to liver and lung. Old dysenteric ulcers in large intestine.

Cod liver oil; quinine; cod liver oil and syrup of iodide of iron; logwood and opium, and opiate enemata for diarrhœa. Locally, opiate poultices, lin. belladonna, and I. P.

Jaundice.—E. G., æt. 37, milliner. Admitted January 21; discharged February 13. In hospital 23 days. *Recovery.* Acute rheumatism 15 years ago; jaundice 3 years ago, and twice subsequently; each attack prolonged. Previously ill one week; shivering; itching of skin; headache; sleeplessness; low of spirits; ocular spectra. On 2nd day after admission, became slightly jaundiced. Gall-bladder distended and painful on pressure.

Aromatic spts. of ammonia; chloric ether and bicarbonate of soda; quinine and dilute muriatic acid; grey powder and rhubarb. Hydrochloric acid lotion over liver.

Jaundice.—Julia N., æt. 68, married. Admitted November 16. *Died* November 17. In hospital one day. Was in King's College Hospital last summer under Dr. Beale, for dyspepsia. Since discharge much pain in epigastrium and frequent vomiting; 12 days ago was seized suddenly with violent pain in hepatic region, recurring 2 and 4 days later. On admission very emaciated; slightly jaundiced; great pain and tenderness in upper part of abdomen; tongue dry; double bruit over base of heart; pulse 100, collapsing. On day after admission was seized with severe pain and vomiting, followed by exhaustion and death.

Post-mortem.—Heart nine and a quarter ounces; left ventricle slightly hypertrophied; mitral and aortic valves somewhat thickened; a bony nodule at base of one aortic valve, and bony plates in aorta; liver clay-coloured and small, its ducts full of bile; gall-bladder distended to size of a large pear; two gall-stones in it; mucous memt. ulcerated; recent lymph on its peritoneal surface; a small gall-stone impacted in lower end of common duct.

Stimulants. Enemata.

Cirrhosis of Liver.—R. S., æt. 45, law-writer. Admitted July 19. *Died* on July 22. In hospital 3 days. Has drunk gin freely. Ascites 3 months; legs œdematous 3 weeks. On admission considerable ascites and œdema of legs; superficial abdominal veins much enlarged; skin dry, slightly sallow; urine scanty and bilious, not albuminous; dulness and large crepitation at bases of lungs; liver dulness as high as fourth rib in front. Pulse 108; appetite bad; tongue furred. On second day after admission 517 ounces of fluid were drawn off by tapping. Sunk, and died next day.

Aromatic spts. of ammonia, chloric ether, sp. junip. co. and liq. ammon. acetatis. Pepsine and hydrochloric acid. Purified ox bile. Paracentesis abdominis.

Cirrhosis.—T. K., æt. 42, miner. Admitted September 30. *Died* on October 24. In hospital 24 days. Has drunk spirits freely. Ten weeks ago, vomiting, diarrhœa, loss of appetite, and debility; dropsy 1 month, commencing in legs; motions loose and frequent, sometimes bloody; slight jaundice; legs œdematous; much ascites (girth at umbilicus, 38½ inches); skin of genitals, abdomen, left chest, left axilla, and inside of left arm, deep purple (began in left axilla 7 days ago); large crepitation and sibilus over chest; tongue brown in centre; red at tip and edges; pulse 96; urine bilious; no albumen. The jaundice ascites and dyspnœa increased, and he died on the 24th.

Post-mortem.—Much turbid serum, the colour of yolk of egg, in peritoneum; liver contracted, fissured and nodulated, bright yellow on section; weight seventy-three and a half ounces; lungs much congested; some patches of pulmonary apoplexy in lower lobes; heart healthy; stomach rather inflamed.

Chloric ether and carbonate of ammonia (19 days). Then hydrocyanic acid and bicarbonate of soda. Turpentine stupes.

Cirrhosis.—Granular Kidneys.—G. G., æt. 65, compositor. Admitted May 25. *Died* June 25. In hospital 31 days. Intemperate. Jaundice 25 years ago; cough and shortness of breath 3 months; œdema of legs and great dyspnœa, 10 days. On admission slight ascites, legs œdematous; dulness and crepitation under right clavicle and over right supra superior fossa; wheezing elsewhere; expectoration frothy, viscid and puriform; pulse 110; respiration 36; urine albuminous; became weaker; passed much clotted blood by rectum on 28th day after admission. Died 3 days later.

Post-mortem.—Much fluid in pleuræ and peritoneum; lungs œdematous and emphysematous; old chalky bodies and cicatrices in their upper lobes; liver 43 ounces; slightly granular; contracted and tough; deep oblique fissure on upper surface of right lobe; kidneys granular and contracted; cysts in cortex.

Chloric ether, carbonate of ammonia and senega. Logwood, sulphate of copper, and opium.

ST. GEORGE'S HOSPITAL.

Dr. OGLE'S CASES OF ABDOMINAL TUMOURS.

Nothing in the whole art of medicine is involved in greater uncertainty than certain tumours in the abdominal regions. Some of the most obscure cases have been very patiently investigated by Dr. J. W. Ogle, who published his conclusions and full details of the cases in the last volume of the St. George's Hospital reports, upon which we have previously drawn so fully. We now purpose to give an epitome of these important cases for the benefit of such of our readers as have not already studied them, and as an encouragement to others to work in the same field. We have only to preface the cases with our thanks to Dr. Ogle for his kind assistance in the matter.

Case I.—LARGE TUMOUR FORMED BY THICKENING AND TUCKING-UP OF THE OMENTUM, WHICH WAS OCCUPIED BY SCROFULOUS DEPOSIT.

F. K., æt. 47, admitted August 17th, 1843, and died December 11th. No history of the case was obtainable, but the preparation may be seen in the museum of St. George's, and the post-mortem found in the books as follows :—

Post-mortem examination.—The whole of the subperitoneal areolar tissue (visceral and parietal) was thickly studded with miliary tubercles. The large omentum was very much thickened by a similar deposit, and being tucked up, *formed a large tumour* situated to the right of the umbilicus, on a level with it. This tumour was united by recently effused fibrin to the anterior wall of the abdomen ; and the various coils of intestine were similarly united. No ulcerations of intestine existed. Here and there was a small quantity of serum between folds of intestine, which had not been united, forming a *species of encysted dropsy.*

The left lung at its apex contained numbers of miliary tubercles and a vomica. Right lung and heart healthy.

Case II.—DISTENSION BY SERUM OF THE SMALLER OMENTAL CAVITY, WHICH WAS CONVERTED INTO A SHUT SAC BY CLOSURE OF THE FORAMEN OF WINSLOW : PECULIAR DEPOSIT BENEATH THE PERITONEUM.

J. I., æt. 39, admitted March 24th, 1841, and died August 26th. As in the former case, no history exists.

Post-mortem examination.—The peritoneum of the whole of the intestine, liver, and other organs, and also that lining the abdominal walls, was covered by a thick layer of fibrin, which could be scraped off ; also beneath the peritoneum of the bowels and parietes a quantity of black material was deposited. The upper cavity of the omentum had been converted into a shut sac by a false membrane which blocked up the foramen of Winslow ; and the cavity of this sac contained a quantity of straw-coloured serum. The liver, spleen, and kidneys were much diseased.

The left ventricle of the heart was much thickened ; and much disease of the mitral valve and œdema of the legs, with fluid in the pleural and pericardial sacs, existed.

Case III.—LARGE MASS OCCUPYING THE CENTRE OF THE ABDOMEN, FORMED BY HYDATID CYSTS CONNECTED WITH THE OMENTA. CAVITY, LINED BY FIBRIN, AND CONTAINING PURULENT FLUID, FORMED BY BREAKING DOWN OF THESE CYSTS. PURULENT DEPOSITS IN THE LIVER ; PUS IN THE PORTAL VEIN.

Josiah S., æt. 38, was admitted Jan. 30, 1850. For many years he had not been quite well, and also had been getting large in the abdomen ; but on the whole enjoyed fair health, until one week before admission, when he experienced severe pain in the region of the liver, epigastrium, and right shoulder. He had several times had rigors. When admitted, the skin was brownish yellow, and the abdomen was very large and hard, with rounded nodulated tumours, to be felt through the parietes, almost over its whole surface. Extensive dulness, continuous with that of the liver, extended very high into the chest, and passed across the umbilicus to the left iliac region, but nowhere could any edge be discovered ; and though there was much softness, no positive fluctuation could be detected. There was some resonance in the left hypochondriac and iliac regions. The urine was very dark and very albuminous. The conjunctiva yellow. Purgatives were freely given, and ether to alleviate a spasmodic kind of pain of which he complained ; the alvine evacuations were very pale. Though in some respects he improved, the abdomen became larger. The albumen and bile diminished in the urine, but œdema of the legs came on, and then diarrhœa. He lost strength and flesh ; and pain in the lower part of the abdomen was great. He finally became delirious before death, which occurred Feb. 2nd.

Post-mortem Examination.—The lungs were somewhat conjested ; the right one being much pushed up by the liver which reached as high as the third intercostal space.

The great omentum was at its lower part adherent to the anterior wall of the abdomen. In the areolar tissue, between the layers of peritoneum, forming the lesser and greater omentum, were numerous cysts containing hydatids which formed an enormous mass, occupying the whole of the central part of the abdominal cavity, and much displacing the viscera ; the small intestines occupying chiefly the left iliac fossa. Behind the umbilicus, in the anterior and lower portion of the mass of cysts, was situated a large irregular cavity of sufficient capacity to contain a child's head. This cavity was apparently formed by the coalescing of several cysts, the interposed partitions having been destroyed. It was lined by a thick layer of false membrane, which gave great consistency to its walls, and it contained a thin yellowish, purulent, and very offensive fluid, in which floated many hydatids, apparently long dead. The remainder of the mass consisted of cysts containing hydatids, some ruptured and collapsed, others in various stages of development. The containing cyst-walls were in places almost of fibro-cartilaginous character. Isolated cysts also existed ; as, for example, in the transverse meso-colon, beneath the peritoneum of the sigmoid flexure of the colon, between the rectum and bladder, between the peritoneum and the fascia transversalis near the umbilicus.

The liver contained several small purulent deposits, slightly tinged with bile, and the *branches of the portal vein* also contained pus. Kidneys congested. Other organs natural.

Case IV.—LARGE SAC, FORMED OF FIBRINOUS MATERIAL AND FILLED WITH FLUID ; SITUATED IN FRONT OF THE INTESTINES.

Jane L., æt. 29, admitted May 8, 1850, with ascites and diseased liver. At first the swelling, as she said, had appeared to begin on the *left* side, where pain existed ; and for some time she thought she had been pregnant. When admitted, the abdomen was enormously distended, and no resonance existed at its upper part, but it could be traced on either side towards the spine. Tapping had to be resorted to several times.

Post-mortem Examination.—The cavity of the peritoneum was found lined by a tolerably thick layer of firmly organised lymph, which passed in front of the intestines and formed a sac, filled with yellow serum. Numerous slender bands of recent lymph were stretched across the sac. All the abdominal organs were matted together, and bound down to the back of the cavity by old adhesions.

Case V.—CYSTS FILLED WITH SERUM, FORMED BY FIBRINOUS LAMINÆ INTERSECTING THE GENERAL PERITONEAL CAVITY, THE RESULTS OF PERITONITIS. LARGE CYST OF THE RIGHT OVARY ; SMALLER ONES OF THE LEFT OVARY.

Mary T., æt. 34, the mother of eight children, was admitted October 19, 1853, with a swelling of the abdomen, which she said had been attended with most pain on the right side. The catamenia had been regular ; she had had no illness. The abdomen was very generally and uniformly distended, and fluctuation was manifest ; the resonance of the bowels always occupying the most prominent parts of the abdomen when she changed her position. There was no evidence of disease of the heart or kidneys. Under the use of diuretics and purgatives the abdomen was reduced almost to the natural size ; and she left the hospital, but continued as an out-patient. On the 19th of October she became again an in-patient, having a very large abdomen, and suffering from pains therein, and from vomiting, with constipation. The resonance of the bowels was only to be heard very high up. Still there was no anasarca, and the urine was free from albumen though scanty. Paracentesis abdominis was performed, and much clear limpid fluid withdrawn. She went on pretty well for some days, until thirst and vomiting came on, and symptoms of some degree of peritonitis. She became low and depressed, and, in spite of certain favourable changes, sank, and died December 2nd.

Post-mortem examination.—There was some œdema of the lungs behind, but the various thoracic organs were natural. The abdomen contained a large quantity of straw-coloured fluid, enclosed in spaces formed by fibrinous laminæ intersecting the peritoneal cavity; so that, in making a puncture into one of these, the fluid escaped from that space alone. The parietal peritoneum was lined by a thick layer of vascular false membrane. The intestines were contracted, and accumulated into a very small space in front of the spine. The kidneys were healthy; the liver small, with an opaque capsule. A large cyst, of the size of a fœtal head, was connected with the right ovary, and occupying the pelvic cavity: this was filled with dark gelatinous fluid and soft vascular solid masses. Several small cysts were also connected with the other ovary.

Case VI.—PERITONITIS. PECULIAR FETID GRUMOUS FLUID, OF UNCERTAIN ORIGIN, IN THE DEEP CAVITY OF THE PERITONEUM.

Mary H., æt. 45, was admittd July 18, 1858, in a dying state, and suffering from great tenderness over the whole of the abdomen and sickness of three days' standing. The bowels had been confined, but had operated three days previously. No hernia could be ascertained to exist. She died in great suffering a few hours after admission.

Post-mortem examination.—The heart was very flabby, and a small quantity of atheroma existed on the anterior flap of the mitral valve. The other thoracic organs were natural.

The various coils of small intestine and the abdominal viscera were adherent to each other by recent adhesions, and the cavity itself (where not obliterated by other adhesions) was filled with a fetid grumous fluid much resembling the contents of the small intestine; and, as the adhesions in various parts of the cavity were broken down, this fluid oozed out from circumscribed cavities in the peritoneum, giving, at first sight, the impression that the intestine was perforated. This was, however, not the case, as the internal surface of the intestine, examined all the way from the stomach to the anus, was nowhere diseased, though the external surface was covered by lymph and inflamed. The subperitoneal areolar tissue was occupied by a peculiar deposit, of a strongly fetid odour, and of a grumous character, the origin and nature of which was uncertain.

The stomach and other abdominal and pelvic organs were quite healthy.

Case VII.—ENORMOUS SOFT ENCEPHALOID TUMOUR, WEIGHING 30 LBS., CONNECTED WITH THE GREAT OMENTUM. A FEW NODULES OF THE SAME CONNECTED WITH THE MESENTERY. OTHER ORGANS NATURAL.

J. B., æt. 42, was admitted November 22, 1865, having had "a swelling of the stomach" six weeks. It appeared that he noticed it first in the region of the ilio-cæcal valve; and that it was attended by vomiting, but was accompanied by some pain; the bowels having been regular. On admission, a large, soft, quaggy, ill-defined, smooth, superficial tumour, free from pain or tenderness, existed at the lower part of the abdomen. The urine was natural; the bowels were opened (the evacuations appearing as if they had been long retained), and the tumour seemed smaller afterwards; but they were sluggish, requiring strong purgatives. The belly became more swelled and tense, but the general health did not suffer. No fluctuation was found, but the whole anterior of the abdomen was dull on percussion (not otherwise, on change of position), the flanks being resonant. The distension became much increased by flatulence. On the 25th of January, vomiting for the first time set in, and continued until death. He now began to lose flesh and to become unhealthy-looking; the bowels only acted by enemata. He sank and died January 28th.

Post-mortem examination.—The thoracic organs were natural. The abdominal walls were adherent to a large mass beneath. After the adhesions had been removed an enormous tumour of soft encephaloid carcinoma was found occupying the whole front of the belly, extending from the diaphragm to the pubes. This was connected with the great omentum, and could be turned out of the cavity so as to display the viscera behind. The mass was divided into lobules, so that it had a very close resemblance (in appearance as well as consistency) to the surface of the brain. It weighed 30 lbs. A few small nodules, varying in size up to that of a walnut, of similar material, were met with in the mesentery, and attached, in some parts by pedicles, to various folds of peritoneum.

The other organs were natural

Case VIII.—QUANTITY OF A PECULIAR MATERIAL, RESEMBLING DEGENERATED FIBRINOUS DEPOSIT, SITUATED BENEATH THE PERITONEUM, LINING A LARGE PORTION OF THE ABDOMEN.

Emma F., æt. 35, an intemperate woman, was admitted January 25, 1866. She had rheumatic fever fourteen months before, and since that she had been low and weak. She had been for two weeks suffering from sickness and dyspepsia, when, during the catamenial period, she was attacked with cold and was seized with pain in the region of the uterus; and, on admission, had much pain in the lower part of the abdomen, and was constantly retching. There was much distension and some tenderness of the abdomen generally. The urine was not albuminous. Her symptoms were at first relieved by calomel and opium, and turpentine fomentations. Later on, she had symptoms resembling those of incipient delirum tremens. At the right side of the navel some kind of substance was felt within the abdomen, which was painful on pressure. Diarrhœa became very great, and her aspect became jaundiced. She constantly had pains above the pubes; the tongue was furred and the pulse weak; the pupils were very small; and she gradually sank and died.

Post-mortem examination.—The lungs were found loaded with frothy fluid. The heart was natural. On examining the abdomen, a large quantity of what resembled decolourised fibrin was found lying behind the peritoneum, extending from the diaphragm to the brim of the pelvis, lying in front of both kidneys and around the duodenum, and also to a certain extent penetrating into the mesentery and being in close relation with every part of the colon. It was abundant about the pancreas and suprarenal capsules, and closely surrounded the large vessels of the liver and spleen. Here and there, in the immediate neighbourhood of this deposit, were small circumscribed pustules below the peritoneum; one, of small size, lay just under the mucous membrane of the large bowel. In some places the above-described material was white, like mortar; in others, of a reddish or brownish colour. *Microscopically* examined, it had all the characters of degenerated fibrin, and contained no pus or blood-corpuscules. No source of this deposit could be discovered; no aneurusm nor disease of the bones of the back or pelvis existed, and no traces of peritonitis. The liver was soft, and of a somewhat orange tinge; the kidneys were natural.

Case IX.—SMALL HARD ENCEPHALOID MASSES SPRINKLED OVER LARGE TRACTS OF THE PERITONEUM ONLY; THE SAME CONNECTED WITH THE PLEURAL SURFACE OF THE DIAPHRAGM.

Rose P., æt. 55, was admitted March 23, 1863. She had observed an enlargement in the lower part of the abdomen for three months, which had gradually spread over the whole body, creating only slight pain, but much uneasiness and occasional vomiting. On admission, the abdomen was distended with flatus, and a large mass—without, however, any distinct edges, and which appeared to belong to the *whole abdominal* cavity—was found. *No fluid* could be detected; and pressure only occasioned pain down the right side. The urine was high-coloured, not albuminous; the evacuations from the bowels were natural. In spite of treatment, she got thinner and more pain came on; vomiting and tenseness of the abdomen followed, and she sank, and died April 12th.

Post-mortem examination.—The peritoneal cavity contained a large amount of clear serous fluid. Scattered upon the peritoneum, in *every part*, were numerous white firm deposits, as large as a pea or mustard-seed, resembling hard encephaloid carcinoma. These small bodies were chiefly abundant in the great omentum, and the folds of peritoneum about the uterus were much thickened by similar, but softer, deposit. The liver was contracted and adherent to the diaphragm by adhesions, and on the upper or pleural surface of the diaphragm were several large deposits of the same kind as that attached to the peritoneum.

A very small growth also was found under the capsule of one kidney; but none of the viscera contained any.

Microscopically examined, the deposits were found to consist of small cells, mostly without nuclei; some with a single one.

CASE X.—PULSATING TUMOUR IN THE EPIGASTRIUM FORMED BY SCIRRHOUS OF THE PYLORUS OF THE STOMACH; SCIRRHOUS ALSO OF OTHER PARTS; SCROFULOUS DEPOSIT AND VOMICÆ IN THE LUNGS; EPILEPTIC ATTACKS.

Elizabeth D., æt. 46, was admitted February 13, 1847, with symptoms of disease of the stomach, having pain there after eating, pyrosis and frequent vomiting, chiefly after food, but at other times also. For two months she had perceived a tumour at the epigastric region, which on her admission was of about the size of a walnut. It was then quite circumscribed, painful on pressure, and situated a little above and to the *right* of the umbilicus. It pulsated as if from transmitted impulse. Shortly after admission the patient had an epileptic attack, followed by raving delirium. Then other convulsive attacks subsequently occurred, during which the *pupils were contracted* to the size of a pin's head, and again became dilated when the fit ceased. She became weaker, and died February 18th.

Post-mortem examination.—The tumour of the abdomen was found to be the pyloric end of the stomach, contracted and surrounded by scirrhous deposit, which internally was ulcerated; the omentum adjoining contained similar deposit. Similar scirrhous tubercles also existed beneath the peritoneum, covering the liver, spleen, and one kidney. In the substance of one kidney was also a small tumour of the same nature. Lungs congested and somewhat emphysematous. One vomica. Brain softened and contained much serum.

EAST LONDON CHILDREN'S HOSPITAL.—This thriving special institution for children at the East end of London began its work with eight beds in January last. Within a few months the number had increased to twenty-six, and the applications for admission have shown how much work there is to be done by the little hospital. We learn from the first annual report that during the last six months 90 in-patients have been received, and 2300 out-patients attended to. The free-hold of the hospital has been generously purchased for £2000 by Mr. and Mrs. Heckford. The institution had our approval at the outset of its career, and we can only repeat that it is fully entitled to the support of the public.

As Mr. Hains, Surgeon, of Totnes, was attending the bedside of a patient at Harberton, the portion of the flooring on which he was standing suddenly gave way, precipitating him into the room beneath. Happily, beyond being shaken and receiving some slight bruises, Mr. Hains was not much the worse. Mr. Hains is a gentleman of unusual weight and rotundity.

THE AILMENTS OF THE MEDICAL BODY CORPORATE.

No. I.

THE MATERIEL OF THE PROFESSION.

IN proceeding to ask and answer the categorical enquiry, " Is a doctor a gentleman," as the first stage in our proposed discussion of the ailments of the Medical Body Corporate, we aim rather at putting the issue in a decisive than in a flattering form before the profession; and while we are glad to believe that the inuendo of our query implies an unmerited slur on a great proportion of our brotherhood, we are feign to confess that in the public valuation of the profession, a sufficiently inferior social estimate attaches to doctors, viewed in the abstract, to justify us in meeting the prejudice face to face, and discussing it in a spirit of belief, and with the hope of thoroughly probing the offensive *cloacæ* which mar the social health of the profession.

It can hardly be said that a profession which for ten years has paid for, and with still greater self-sacrifice, even listened to the uninstructive wranglings of the Council of Medical Reform, is unconscious of its corporate rottenness, or lethargic over its unfortunate sanitary condition. That after a ten years' puzzle of the medical brain over the medico-educational enigma, the professional body should not have become thoroughly sick and careless of the subject, proves that the condition which has called forth the debate is thoroughly well recognized, and the attainment of a remedy foremost in the aspiration of our brethren.

Are we certain that we have not been all along looking too remotely for the disease and its treatment while its final cause is right before us? In discussing the palpable causes which make a good student into a bad doctor, have we forgotten to inquire whether the *materiel* of the student *is* good, in other words, whether the class from which the embryo doctor comes is always such as to give a fair ground for the fructification of the educational seed which is now credited with the poorness of the harvest?

We are not as medical journalists charged with the duty of making things pleasant for the profession, or tickling the vanity of medical students, either in the raw or finished form. We do not desire to make ourselves ridiculous, by pretending to deny that which is patent to all the world, nor do we think the extra-professional public will think the worse of us for calling our faults by their proper names. The simple fact is that the class from which medical students come is not always such as gentlemen are made of, and no system of subsequent education however perfect, could be expected to confer social qualities on the man which the boy either takes away with him from school, or else never possesses.

In innumerable instances medical education, with talent and industry, do everything that can be hoped for; but they cannot effect that which, for the Profession at large, is most to be hoped for. They make a skilful Surgeon, an original-minded and astute Physician, a thoroughly experienced and reliable medical attendant; but they always fail to make a gentleman where the nameless and indefinable combination of gentleness, honour, and fine feeling embodied in that title does not already exist. The utmost energies of teachers, students, and examiners can only bring the medical man into *professional* contact with the first class of his patients; they can insure to him respect and confidence as a master in his art, and afford him the monetary reward of his work and labour done, but without the self-contained qualities which make a gentleman, they never can raise the doctor to the level of a personal friend, or confer the influence and social position which the Profession at the present day wants more than anything else.

Why is it that the public influences of the Profession as a body are so painfully insignificant? Why is our representation in State—honour—emolument, or confidence below that of any other profession? Why is it that the Departmental snub is administered to the doctor with more insolent disregard of his feelings than to any other class of suppliant?

The social status of doctors in the aggregate supply the answer, and suggest the remedy. If the *personel* of the medical man, as it is in too many instances, is but slightly removed from that of the local druggist; if he estimates the pecuniary value of his own services in greatly inferior proportion to that of the Church or the law; if he is not protected from degrading practices and dirty little meannesses by a proper sense of self-respect or a painful consciousness of shame, how is it to be supposed that gentlemen of mind or ladies of good breeding will disassociate him from the local druggist, or that governments will open their ears to his complaints as they do to those of the Church or the law. And experience corroborates our theory, for the branch of the profession into which gentlemen introduce their sons is that portion of the body corporate whose status protects it from the social faults of which we have spoken, and which accordingly enjoys all the social equality and all the public influence which medicine can now boast of.

No doubt the grievance of which we complain represents more or less the whole disease of the profession—no doubt the inferior status of a section of the profession is the natural result of the cheapening and underselling system which opens the ranks of our body as a resort for persons, the deficiencies of whose person and education render their success elsewhere very doubtful. We are well aware that the profession cannot be composed solely of gentlemen as long as licensing corporations are happy to accept illiterate vulgarians if they cannot get gentlemen, and five shilling diploma fees if they cannot get guineas. What we desire to convey by our argument is that in a social direction much more is wanting to the profession than mere medico-educational reform, and that, if the Utopia of educational perfection should ever be reached, the profession will still have advanced little or nothing in respect of its status. We do not ask that medical education should be made more expensive, for such a movement, while it excluded that class who have the greatest incentive to industry, would admit others, who though thoroughly competent to pay, would do no social credit to our body. We demand that the only test within the power of those who hold the entrance-keys of the profession—mental culture by a liberal education—shall be exacted. If we secure that, the candidates for admission shall possess such mental acquirements as their *confreres* in law and divinity can show. If we make certain that they shall not openly disgrace the body by caddishness or palpable ignorance, we shall possess a sufficient guarantee that the discipline which their minds has undergone will protect them and us from any practice which might degrade medical men in the public estimation. Let us make sure that the doctor shall write and speak the English language with no fewer H's than his compeers of the Church or the law, and shall be as competent as they are to give expression to his ideas on the ordinary topics of conversation, and we may rest satisfied that he will be as readily received into good society as the rector or the lawyer, and will never depreciate his position by mean or unworthy practices. When we have demanded and obtained in the Candidate such attributes, it will be an easy task even with the multitudinous deficiencies of the teaching system to make him a competent surgeon or a reliable physician.

A FEW WORDS ABOUT FEES.

MANY of our readers have, doubtless, perused with pleasure Sir WALTER SCOTT's inimitable description of Doctor LUKE LUNDIN, in that admirable novel of "The Abbot."

The Doctor is depicted as a fussy, empty-headed, good-for-nothing medicus, whose head was stuffed with Latin aphorisms and proverbs, but whose skill, when required in a case of supposed poisoning, was weighed in the balances, and found wanting.

This doctor found in his day, as many a physician has found in ours, that however popular the Doctor may be in time of illness and nature's extremity, once the patient is cured and the disagreeable question of fees comes to be considered, he is straightway voted a bore, and is not rarely treated with barefaced ingratitude.

In one of Doctor LUKE LUNDIN's walks he meets some of his patients, whereon the novelist proceeds thus:—"The next whom the Doctor deigned to take notice of was a lame fellow, by whom the honour was altogether undeserved, for at sight of the mediciner he began to shuffle away in the crowd as fast as his infirmities would permit.

"'There is an ungrateful hound for you,' said Doctor LUNDIN; 'I cured him of the gout in his feet, and now he talks of the chargeableness of medicine, and makes the first use of his restored legs to fly from his physician. His *podagra* hath become a *chiragra*, as honest MARTIAL hath it—the gout has got into his fingers, and he cannot draw his purse. Old saying and true—*Præmia cum poscit Medicus, Sathan est.* We are angels when we come to cure, devils when we ask payment; but I will administe a purgation to his purse, I warrant him.'"

Need we point the moral? probably not; for what medical man engaged in active practice has not found Sir WALTER SCOTT's description time to life, and few there are who have not experienced in their own persons, at some time or other, the feelings of the Scottish medicus who said, in words which ought to pass into a proverb, "We are angels when we come to cure, devils when we ask payment."

The best way to meet this spirit, against which we protest, is to urge our first-class physicians and surgeons to be clear and distinct in stating and demanding their fees, letting the old and unsatisfactory plan of "leaving it all to yourself" alone. Many do this, and as a necessary consequence, their services are highly valued, while the services of their more complacent but less firm brethren are rated by the public, as they themselves rate them.

A Dublin physician of eminence, not many years ago, demanded and got his honorarium of two guineas per visit, no matter how often he went to see the patient. On its being objected to him that the number of visits made his fees come high, he replied, "You do not really require *my* services; there are many younger men who will serve you as well for less, and if you wish for *me*, you must have me on my own terms. If I should visit at a low rate, what would become of my professional juniors?"

◆

Notes on Current Topics.

The Public Health.

The usual periodic return has been issued by the Registrar-General, and contains the following statistics:—

In the week that ended on Saturday, August 29th, 4730 births, and 3364 deaths, were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 27 per 1000 persons living. The annual rate of mortality last week was 23 per 1000 in London, 24 in Edinburgh, and 28 in Dublin; 19 in Bristol, 30 in Birmingham, 36 in Liverpool, 39 in Manchester, 35 in Salford, 36 in Sheffield, 32 in Bradford, 39 in Leeds, 32 in Hull, 30 in Newcastle-upon-Tyne, and 26 in Glasgow.

In London the births of 1121 boys and 1126 girls, in all 2247 children, were registered in the week. In the corresponding weeks of ten years, 1858-67, the average number, corrected for increase of population, is 1993. The deaths registered in London during the week were 1356. It was the thirty-fifth week of the year; and the average number of deaths for that week is, with a correction for increase of population, 1318. The deaths in the present return exceed by 38 the estimated amount, but are less by 72 than the number recorded in the preceding week. The deaths from zymotic diseases were 432, the corrected average number being 462. Seven deaths from small-pox, 21 from measles, 57 from scarlatina, 5 from diphtheria, 24 from whooping-cough, and 51 from fever, were registered. The mortality from diarrhœa and cholera is decreasing. Last week the deaths of 174 children and 12 adults from diarrhœa, and the deaths of 10 children from cholera or choleraic diarrhœa, were registered. In the two preceding weeks the deaths from diarrhœa were 245 and 246, and from cholera 29 and 15. The widow of a sailor died on August 25th, at 29, Chilton-street, Rotherhithe, at the age (as stated) of 101 years. The deaths of 2 persons from intemperance, of 3 persons from delirium tremens, of 8 infants and 2 adults from syphilis, of 3 persons from burns or scalds, of 7 persons from drowning, of 2 infants from suffocation, of six persons who committed suicide, and of 5 persons who were killed by horses or carriages in the streets were registered.

The City Police (London).

Many hours of the twenty-four are spent by the policeman on his "beat," whatever the peculiarities of the weather—"hail, rain, or shine"—hot, mild, or cold—day or night, he must be there. His periodic exposure to these changes, and his liability very often to injury and violence might lead to the expectation that his health would necessarily suffer, and his life be proportionably short. In former years there might be some ground for the apprehension, but since the opening of an hospital especially for the members of the force, both the mortality and the severity of sickness among the men has been much less. The medical officer of the city force, Mr. B. Childs, has sent in his returns to the police authorities, for the year ending the 23rd June last, which shows to what extent such has been the case. The city force consists of 697 men, and is distributed into six divisions. That stationed in Moor-lane was the healthiest—that in Bishopsgate-street the least so During the year, 423 were admitted into hospital, five died and upwards of eleven were constantly on the sick list, the diseases being those resulting from exposure. Both the sickness and mortality were found to be less among the married men than the single. The married men numbered 498 and the single 199. Only one death occurred amongst the former, while there were four among the latter. So with admissions to the hospital; the proportions were 469 per 1000 married men, and 934 per 1000 single. A similar though very slight difference is marked between those on day and those on night duty. We cannot quote the whole of Mr. Childs' figures, but it appears from his report that the state of the force under his charge compares very favourably both with the health of the metropolitan police, and with that of the troops in the United Kingdom.

A Medical Man Fined.

Under the 23rd and 30th sections of the Vaccination Act passed in 1867, Dr. David Roberts, of Great Dover-street, Borough, was summoned by the parish authorities of Camberwell, for refusing to fill up and sign a certificate of successful vaccination performed by him. The case was heard at the Southwark Police Court. It appeared that the Registrar of Births and Deaths wrote to him on his refusal, and received a reply stating that he (Dr. Roberts) adhered to his determination not to fill up the certificate, and assigning as his reason that he was not paid for it. This was his plea also before the magistrate, to whom he stated that he vaccinated successfully 600 children in the course of the year, and it would be hard if his time was to be taken up without fee or reward.

Mr. Partridge said it was a question of law, and the defendant did not dispute the facts. He had refused to fill up the certificate because he was not paid any remuneration. After referring to the Act which mentions that no fee should be taken by the public vaccinator or any medical practitioner on giving his certificate, he said there was nothing to show that he had not the remedy of getting his fee as a private practitioner from the party who employed him; but it was clear that he was bound to give his certificate to the registrar without fee. The fine, under the 30th section of the Act, was 20s.; but as the defendant had only come forward to meet the case on those peculiar grounds, he should mitigate it to 10s. and costs.

Dr. Roberts asked his worship to grant him a case for the Court of Queen's Bench, as it was most important to the medical profession.

Mr. Partridge declined to do so, and told Dr. Roberts that if he thought proper he might apply to the Court of Queen's Bench himself.

Over-Laying and Death Certificates.

An inquest held last week on the bodies of two infants, gives us a double text—public and professional—for the discussion of the matter. The mothers of the two little victims excused themselves for the deaths of their children on the ground that they were accidentally suffocated by lying on them, and in the same breath they confessed that they had insured the lives, or rather the deaths, of the infants a short time before. The only evidence besides the statement of the mothers themselves, was the certificate of a surgeon who had never seen either body after death, and yet legally declared that they died of suffocation. The mothers were dismissed to the enjoyment of their gains by the death of the babies, and the surgeon was severely taken to task by the Coroner for certifying that of which he knew nothing.

Medical Capacity for Coronerships.

Dr. Lankester, the coroner for Central Middlesex, has, in the discussion of Dr. Tindal Robertson's late paper at the meeting of the Association, debated the special qualifications of the doctor for the office of coroner in a tone which, though by no means enthusiastic as regards the claims of the profession, is impartial and argumentative. He considers that a medical practitioner is, by his habit of deduction from theory as much as from fact, rather the worse than the better as an investigator of simple occurrences, and he declares that the medical man owes his superiority to his study of the natural sciences. This we believe to be an accurate enunciation of the doctors special qualification, and one which ought not to be overlooked by the public. A medical coroner is an embodiement, in cases in which it is considered unnecessary to hold post-mortem investigations, of the judge and the expert. He is in the position which no lawyer can enjoy, of checking each enquiry by his medico-legal knowledge, and under his supervision it becomes improbable that in any case whatever, suspicious circumstances and pathological appearances could be overlooked. Thus, the public has an extra guarantee for the reliability of a medical coroner's enquiry, which they cannot have at the hands of any other functionary, however astute he may be.

The Medical Act against Quacks.

At last it would appear that the powers of the Medical Act against quacks are discovered to be sufficient for their object, and the action of the profession which was discouraged in the first instance by some very paradoxical legal judgments, is being revived against illegal practitioners. A druggist in Wales has been successfully prosecuted by the North Wales Registration Society, for using the title of Surgeon in a death certificate. The culprit endeavoured to save himself by attaching the letters n. r. to his falsely claimed qualification, which he explained to mean "not registered." The fraud was too manifest for such a ridiculous defence, and the practising druggist has had the option of paying £10 or going to prison for a fortnight. The judgment of a member of the English Bench to the effect that the use of any title was not illegal so long as the culprit did not represent himself to be registered—a decision which has mainly deterred the profession from availing themselves of the provisions of the Act—would thus appear to be incorrect, as it is manifestly at variance with the spirit of the law. It is justly held that a person who uses the title of a medical qualification, thereby implies that he is or might be registered for it, and he should be punished accordingly.

It is satisfactory to find that justice seems likely to overcome the ridiculous legal quiddits which have hitherto rendered the Medical Act nugatory.

Qualification of Medical Assistants.

The Privy Council has had before it a series of new regulations for the examination of assistants, framed in accordance with the recent Pharmacy Act. We understand that the proposed examination combines Materia Medica, Pharmacy, Translation of Prescriptions, and the details of ordinary Dispensing Manipulation. The Materia Medica test will be principally on the identification of chemicals and pharmaceutical agents, both in the officinal condition and in the plant itself, and to pronounce on the quality and adulteration of each article, the candidates will be required to recognise the manufactured preparations, such as tinctures, infusions, and extracts, and to know the relative proportions of the various ingredients. Their capacity for the manipulation part of their duty will be tested by requiring them to translate prescriptions, to point out excessive or insufficient doses in faulty trial prescriptions, and to weigh, make up, and turn out neatly given prescriptions.

Scottish Longevity.

Whether from their occupations, the strength of their constitution, their climate, their diet; whether from all these combined, or from some other hidden and mysterious agency, the Scotch can boast of far more instances of longevity than occur in any other equal portion of the population in the United Kingdom, the returns recently issued by the Registrar-General for Scotland for the ten years 1855-64 show that in that country as many as 6910 of the 651,295 deaths in those ten years were of persons above 90 years of age. The mean population of the period is estimated at not quite 3,050,000. The following notes from Scottish local registrars' returns for the second or spring quarter of 1868, just published, are remarkable:—Stromness, Orkney.—Of the nine deaths registered in the quarter, two were of persons aged 94. Watten, Caithness.—Of the nine deaths, six were of persons above 70; the average age of the six was 80 years. Gairloch, Ross.—Of the 15 deaths in the southern district, eight were of persons above 70, their ages averaging 81. Stornoway.—Of the 37 deaths, 13 were of persons above 70; one was 100. Rafford, Elgin.—Of the three deaths, two were of persons aged 84 and 86. Huntly, Aberdeen.—Of the deaths, eight were of persons above 70, their average being 77. Blanchory-Devenick, Kincardine.—Of the eight deaths, four were of old persons whose ages averaged 78 years. Largo, Fife.—Of the eight deaths, five were of persons aged 78, 82, 83, 84, 85. Kilmore and Kilbride, Argyll.—Of the 19 deaths, nine were of persons above 70. Portobello.—Of the 30 deaths, seven were of persons above 70. Mid-Calder, Edinburgh, population about 1400.—Only two deaths, one of a person of 85 and one of 89. Dunscore, Dumfries.—Of the nine deaths, five were of old people whose united ages amounted to 387 years. Kirkcowan, Wigtown.—Of the eight deaths recorded, six were of persons who had reached the respective ages of 68, 75, 79, 82, 84, 86 years. At Girvan, Ayrshire, a death at 101 was registered in the quarter; at Inverallan, Inverness, the death of a woman of 103; at Abbey, Renfrew, the death of a very old Highland woman, said to be 109.

Professional Appeal.

We deeply regret that adverse circumstances, arising out of illness, make it necessary to appeal in our advertising columns to our brethren on behalf of a well-known and highly esteemed member of the profession in Dublin. We beg to refer our readers to that appeal, which we are confident will not be made in vain. The *res angusta domi* is a possibility in every case, and a fact in many; but we can say of our brother in this instance—"*In prosperis magnus, in adversis major.*"

Antoine Clot-Bey, an eminent physician, died lately at Marseilles, aged 73. He was induced to visit Egypt many years ago by an agent of Mehemet-Ali, for the purpose of organizing some medical establishments there. He also founded a medical school at Alexandria, and was chief agent in the erection of Abou-Zabel's Hospital, twelve miles from Cairo. He received the title of Bey from the Egyptian Government, and by that of France he was made a Commander of the Legion of Honour.

Dr. Samuel Fenwick and Mr. J. E. Adams have been appointed Assistant-Physician and Assistant-Surgeon to the London Hospital.

Lecture.

LECTURES ON VENEREAL DISEASES
DELIVERED IN
DR. STEEVENS' HOSPITAL.

LECTURE IV.

By ROBERT McDONNELL, M.D., F.R.S.,
ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

Gentlemen,—I do not mean to trouble you with any very lengthened observations on the treatment of syphilis. I have already said that the details of treatment must be pointed out at the bed-side, yet I feel that my lectures would very incompletely answer the purpose for which they were intended if I did not briefly touch on some points connected with the therapeutics of syphilis.

As students of the Irish School of Medicine you may look, gentlemen, with very just pride to what has been done in this department by practitioners of Dublin. To Wallace we owe the introduction of iodide of potassium as an anti-syphilitic agent—an agent now universally admitted to be one of the most potent weapons which human skill can wield against this disease in many of its forms; to Carmichael we are indebted for having led the van in opposition to that free and reckless use of mercurials, which has done, and indeed still does so much mischief. He may almost be said to have inaugurated the all-important scientific study of the natural history of syphilis; while Colles, Abraham Colles (whose memory is so highly revered within the walls of this great hospital), has, in his work on "Venereal Diseases and the Use of Mercury," given the most masterly sketch with which I am acquainted as to how we should handle the claymore against syphilis, should it become necessary to draw it from its scabbard.

I shall speak now of the treatment of syphilis, first, as regards measures of simple hygiene, and next as regards that method which is generally spoken of as specific treatment.

Let me, however, before entering on these topics, lay before you some of the conclusions lately arrived at on the subject of syphilisation.

In the last volume of the "Transactions of the Medico-Chirurgical Society of London" you will find a very valuable contribution to our knowledge on this subject by Messrs. Lane and Gascoyen, surgeons to the London Lock Hospital. These gentlemen give a report of cases treated by syphilisation, or the repeated inoculation of syphilitic matter in persons already the subject of constitutional disease. It is true their own opinions do not agree as to the curative influence of syphilisation; the facts, however, which they record are not the less interesting and instructing.

Syphilisation.—This peculiar method of treatment originated with M. Auzias-Turenne about 1845; owing to the opposition of the French Academy of Medicine, it can scarcely be said to have been tested in France, except by the late M. Melchior Robert of Marseilles. M. Sperino, of Turin, tried it in a considerable number of cases. Professor Böeck, of Christiania, however, is at this moment the champion of syphilisation; he has developed the system on a large scale, and the publications of himself and his pupil, Dr. Bidenkap, have revived the interest in this subject.

The strange idea of curing syphilis by repeated syphilitic inoculations had its birth in France. It took its origin in this way—M. Auzias-Turenne, when studying the effects of syphilitic virus upon animals, perceived that after a certain number of inoculations, the inoculated animal gained a power of resisting the chancrous virus. To their immunity from the disease thus established, or rather to the peculiar modification of the organism thus induced, Auzias-Turenne gave the name of syphilisation. In November, 1850, he announced the result to the Academie des Sciences. He naturally conceived that it would not be impossible to reproduce in man the effects which he had observed on the lower animals; some patients voluntarily submitted themselves to his inoculations; in these cases a complete immunity was obtained; and so the ideas of Auzias-Turenne became admitted within the domain of therapeutics.

The practice of syphilisation evoked extreme hostility in England, in fact it was never fairly tried until undertaken by Messrs Lane and Gascoyen, who commenced their series of observations under the direction of Dr. Böeck himself.

These gentlemen pursued the method recommended by Dr. Böeck, which is as follows:—At the commencement three punctures are made on each side of the chest, and matter is inserted derived either from a person who has a primary syphilitic ulcer or from the artificial sores of a patient who is undergoing syphilisation. After an interval of three days, if the punctures have developed pustules, three other inoculations are made from them in the same region of the body, and this process is repeated so long as pustules are produced; the inoculations being made at intervals of three days, and the matter being always taken from the last-formed pustules. When at length these are not inoculable, fresh matter is employed, and the above process is repeated until a positive result can no longer be obtained on the trunk. The same practice is then commenced on the arms and continued there until the punctures fail, when a similar process is pursued on the thighs until no more pustules result, and a condition of immunity, more or less perfect, is arrived at. In the ordinary run of cases this occurs in from three to four months.

The average period during which Messrs. Lane and Gascoyen's cases were under treatment in hospital, was five months and sixteen days. The average number of inoculations practised in each case was 259, of which 145 produced chancres, and 114 were sterile. A method of treatment which entails the production of some 150 chancres over the body can never, I think, be a popular mode of treating syphilis. From a very careful perusal of the valuable memoir of Messrs. Lane and Gascoyen, I most fully concur in the justice of the conclusion at which they arrive as to the therapeutic value of syphilisation. "Differing," they say, "as we do on the scientific aspect of the question, we are entirely in accord as to its practical bearings, and we are decidedly of opinion that syphilisation is not a treatment which can be recommended for adoption. We consider that even if it could be admitted to possess all the advantages claimed for it by its advocates over other modes of treatment, or in many instances over no treatment at all, it would not sufficiently compensate for its tediousness, its painfulness, and the life-long marking which it entails upon the patient."

Has syphilisation any curative effect whatever? It seems strange, indeed, that at this period of the world's history we should not be able at once, and with certainty, to answer this question. Yet, to our shame be it confessed, we cannot. We do not as yet know enough about the simple and undisturbed progress of syphilis to say whether fifty cases of the complaint, with no other treatment than the dietary, rest, regular hours, &c., of an hospital, would take longer to get well than fifty similar cases submitted to syphilisation. Mr. Lane believes that *it does exercise some* beneficial and specific influence over the progress of the disease. Mr. Gascoyen, on the other hand, thinks that the natural tendency to recovery, which an early and uncomplicated constitutional syphilis exhibits with the lapse of time, and under circumstances favourable to the general habit, is sufficient to account for the subsidence of the secondary symptoms during syphilisation. It is gratifying to find so competent an authority as Mr. Gascoyen so deeply imbued with the belief that "an early and uncomplicated syphilis" has so great a natural tendency to recovery. For my part I should certainly agree with him. If the possibility of the spontaneous cure of syphilis be no longer contested, from that moment it becomes difficult, if not impossible, to assign its true therapeutic value to any mode of treatment—syphilisation among the rest. In order to determine whether the cases of cure attributed to syphilisation are not in reality due to the natural progress of the malady, there must be some definite standard of comparison. Hence, the extreme value of cases carefully noted and accurately observed for years, and which have undergone no other than treatment by hygienic measures.

Prophylaxis and Hygiene of Syphilis.—The prevention of syphilis, or at least the attempt to check its ravages, is one of the greatest objects connected with State medicine. The rude machinery for this purpose adopted in Great Britain has until quite recently contrasted most unfavourably with the schemes of our continental neighbours.

The Englishman's respect for personal liberty, as well as a sort of moral instinct which made him unwilling to handle an unclean thing, caused us as a nation to shrink from legislation on such a subject as the control of prostitution. Our soldiers, our naval and mercantile marine, and of course the public, have in consequence suffered to an extent quite incredible. We are, however, commencing a better system. Of this aspect of the prophylaxis of syphilis I do not speak at present.

Various plans have been devised in order to prevent the occurrence of venereal disease in an individual after a suspicious connection. These may almost all be summed up in a few words:—strict attention to cleanliness, thorough washing. There can be little doubt that proper attention to this simple preventive measure would greatly lessen the evils arising from venereal disease of different kinds. A number of practitioners have recommended various lotions with the design of adding to the wash such ingredients as may destroy any venereal virus lurking in the folds, or coming in contact with slight fissures or excoriations around the corona or about the frenum. Lotions containing acids, alkalies, alcohol, wine, sulphate of zinc, lead, &c., have been thus ordered. Langlebert recommends a mixture of soft soap, potass, and alcohol. Rodet of Lyons, a lotion somewhat more caustic, viz.:—

℞ Ferri perchloridi liquoris fortioris.
Acidi hydrochlorici.
Acidi citrici aa. ʒiv.
Aquæ distillatæ fll. ℥iv.
M. Fiat lotio.

How long after contamination the use of such appliances may serve to neutralize a poison remains doubtful. All we can say for certain is that the sooner any poison is washed away or destroyed the better.

When it is once admitted that syphilis is a true toxæmic disease, that it is a malady in fact depending upon the admission into the system of a poison, which, under favourable circumstances, is capable of spontaneous elimination, then it follows that hygienic measures must play a capital part in its treatment. If, as I have said in a former lecture, a struggle is going on between the constitution of the patient and a disease which has made an inroad into his system, it is of course of prime consequence that the constitution should be well backed up in the conflict.

To maintain the general health, to uphold the natural vigour of the constitution, to keep the powers of the organism up to that level which is best adapted to accomplish the elimination of the virus—this is the object of the hygienic treatment. When to this we add the use of those simple medicaments which, acting on the skin, bowels, and kidneys, tend to keep their functions in healthy play, yet are not supposed to exercise any specific action, we then have that plan of treatment which has been called the rational or methodic treatment of syphilis.

As regards diet the syphilitic patient should, as a rule, live generously. He should live on simple and nutritious food, taking as much as his appetite indicates to be sufficient—neither weakening his frame by taking less, nor striving to take more than his stomach can readily deal with. In prescribing a dietary attention should always be paid to the patient's usual mode of living; yet, believe me, you will generally find it necessary to insist on your syphilitic patients living tolerably well, many of them are so imbued with the idea that abstinence is necessary for their cure.

Next, probably, in importance to diet is good air, a well-ventilated sleeping apartment free from damp. The damp and crowded dwellings of the poor exercise a most baneful influence over the complaint.

Let your patient have seven or eight hours sleep of a night; let him give up theatres, balls, card and supper parties; let him have such moderate exercise every day that, without being exhausted or absolutely fatigued, he may be well satisfied to go to bed each night at ten o'clock.

If you have influence enough over your patient to induce him to adhere to such directions; to shun those selfish indulgences which tend to debilitate the frame; and if he has youth and a tolerably good constitution on his side, you may look forward to his case running its course favourably as one of "vérole faible."

If he is one of a delicate family, of a scrofulous or gouty diathesis—then it is all the more necessary for him to leave nothing undone to keep up his general health.

But if, on the other hand, you have a patient to deal with who will not forego his selfish pleasures; who haunts the tavern and the billiard-room, smoking and drinking, breathing foul air vitiated by gas and reeking with tobacco-smoke, during the hours which he should give to repose, let him expect that to him syphilis will come in "all her Gorgon-terrors clad."

As adjuncts to hygiene, such simple medications as cod liver oil, chalybeate tonics, and warm baths play an important part. The first is specially indicated when any strumous tendency exists; the second class of remedies, useful through the whole course of the disease, is particularly called for during those periods of syphilitic chlorosis (chloro-anæmia), so usually the forerunner of an outburst of eruption. Warm baths or vapour baths are the most effective means of keeping the skin in action. Medicated baths of various kinds are eminently useful; baths corresponding with those of the bromated and iodated waters of Kreuznach, the waters of Schlangenbad, Harrogate, Baréges, can be readily obtained in all our cities.

Tonic and exciting medicated baths are of great service in syphilitic as well as other affections of the skin; baths containing iodide or sulphuret of potassium, or arseniate of soda are eminently useful in the anæmia, chlorosis, or rheumatism connected with syphilis.

Dr. Noël Guéneau de Mussy recommends three and a-half ounces of subcarbonate of soda, with twenty grains of the arseniate, in a bath. No unprejudiced practitioner will deny the benefit of the Turkish and Russian baths. We have no means of inducing diaphoresis comparable to these.

Such a bath as the following:—

℞ Ferri sulphatis, ʒij.
Sodæ sulphatis, ʒvi. M.

Dissolve in thirty gallons of soft water at 98° Fahrenheit for a bath—can be readily obtained even at the patient's home; and thus the advantage of the chalybeate and the bath combined.

The bowels should be kept in action once or twice every day : for this purpose, nothing answers better than some of the sulphurous mineral waters made artificially; those of Bagnères-du-Luchon, of Baréges, of Aix les Bains, in Savoy, of Aix-la-Chapelle, have gained a well-deserved reputation. The waters of Kreuznach are greatly praised against the intractable combination of syphilis and scrofula. I very commonly order the following imitation of the Harrogate sulphur water—

℞ Sulphatis potassæ, cum. sulphure, ʒiv.
Bitart. potassæ, ʒij.
Sulphatis magnesiæ, ℥iij.
M. Fiat pulvis.

one teaspoonful of this powder to be taken in a tumbler of water every morning, or every second morning upon first getting up. The dose should be increased or diminished according to its effects. The patient should take a short walk before breakfast, and by increasing the quantity of fluid which he consumes daily, he should keep the kidneys in good action.

Syphilitic patients are themselves sometimes aware of a peculiar, faint, yet disagreeable, odour emitted from the urine ; this is observed at intervals, and after each has passed away the patient finds himself better. It seems to resemble the odour which patients labouring under ague know as indicating the approach of an attack of fever; and certainly points to the necessity of keeping these organs in good working order.

Some patients object to the large quantity of liquid necessarily taken in consuming mineral waters, and although this is one of the great advantages attending their use, you may have to direct something else ; equal parts of syrup of senna and fluid extract of sarsaparilla : a teaspoonful once or twice a-day in half a cup of hot water, acts well as an aperient, and suits those persons, not a few, who still retain an unbounded faith in sarsaparilla.

Chlorate of potash used internally, as well as a gargle and mouth wash, is a great favourite with some. For the slighter forms of sore throat, I often order the following :—

℞ Potassæ chloratis, ℥ii.
Mellis ℥i.
Aquæ ℥xi., M.

to be used as a gargle several times a day, and one ounce to be swallowed three times a day.

The doses ordered to be taken internally should be swallowed slowly, in fact, taken in sips, so as to be brought well in contact, in the act of swallowing, with those parts of throat and fauces not reached in gargling.

The importance of the local treatment of all kinds of venereal sores, whether primary, secondary, or tertiary, cannot be over-rated. You have seen abundant proof of this in the terrible case of rupia, lately in No. 9 ward. The ulcers were so extensive that it was impossible to deal with all at the same time. You saw those which were touched with nitric acid, and afterwards dressed for some days with creasote ointment, healed rapidly, far outstripping those less energetically treated.

You have often seen the almost magical effect of a large blister upon the hideous lupoid ulcerations of tertiary syphilis. I have seen some cases in which the local action of an accidental attack of erysipelas has entirely altered the appearance of the ulcer and brought about rapid cicatrization.

In short, whether in the genitals, the mouth and fauces, or the skin, the local applications to venereal affections, forms a chief part of the therapeutics of syphilis. Prohibit tobacco-smoking, and the source of irritation once removed, "mucous patches" and ulcerations on the tongue, &c., for a long time recurring, will get well. Wash the surface, attend to cleanliness, and simply dust the part over with finely powdered starch, and you will quickly get rid of troublesome condylomata. Learn to overcome the more frequent and troublesome symptoms of syphilis, let your patient know that in the natural course of things he must expect recurrences ; do not make promises that relapses are at an end : by so doing you are pretty certain to get a disappointment, and to lose the confidence of your patient, and that equally whether you adopt a specific treatment or not.

The beneficial action of iodine in the treatment of syphilis is beyond doubt ; in some eruptions, in severe syphilitic rheumatism and most forms of tertiary syphilis, its efficacy is unquestioned. In 1831, Lugol published his observations on tertiary symptoms cured by iodides without the combined use of mercurials. This led the way to what must be considered the greatest discovery in syphilitic therapeutics of modern times—namely, the introduction of iodide of potassium as a remedy against syphilis. I have already said that it is to Wallace of this city that mankind is indebted for this boon.

I am glad to find that Lancereaux, one of the most learned and accomplished writers who has treated of the subject of syphilis, gives, in his exhaustive work, full credit to Wallace for being the first to introduce in practice this agent.

Lancereaux says :—"Wallace, of Dublin, has the merit of having first employed iodide of potassium, of having fixed the doses of it, specified the indications for its use, and thereby of having definitely introduced the iodide into the therapeutics of syphilis, placing this medicament almost upon the same level with mercury. He commenced his experiments in 1832, and gave the results four years later in the form of four lectures.[1]

"One hundred and thirty-nine patients were observed, of whom six were affected with iritis, six with affections of the testicle, ten with divers diseases of the bones and articulations, ninety-seven with syphilitic skin affections, twenty with lesions of the mucous membrane of the mouth, nose, and throat ; finally, three pregnant women were also submitted to the same treatment with the object of preserving the fœtus from syphilitic infection. The preparation employed *mistura hydriodatis potassæ* (as it was then called), contained ʒij. of iodide of potassium in ℥viii. of distilled water. Adults took half an ounce of this mixture four times a-day—that is to say, thirty grains of the iodide per diem." Lancereaux adds, "The happy effects of this remedy are so generally recognised, that we cannot refuse to it, in the present day, a place alongside of mercury itself."

Wallace's success soon attracted the attention of other physicians. In England, Judd, Savile, Winslow, Williams ; in France, Trousseau, Ricord, Gauthier ; in Italy, Brera, Sperino, Pellizzari ; in Germany, Guzman made trial of it and proved its good effects.

The acute observation of the illustrious Ricord soon detected that it is an agent which exercises more influence over tertiary than secondary symptoms. The deeper affections of the skin and mucous membranes, the gummy tumours of the cellular tissue, the lesions of the bones—such are the conditions which yield most readily to the use of iodide of potassium. It has been likewise recognised that it may advantageously be employed even in larger doses than those at first recommended by Wallace; by degrees it may be increased from 15 grains to one drachm or even more daily.

---

[1] See *Lancet*, March, 1836.

You have lately seen in No. 8 Ward a remarkable instance of the efficiency of this medicine in the case of a woman named Looney suffering from nodes and very distracting osteocopic pains. She was ordered 10 grains three times a-day, but by mistake took double that dose, taking 60 grains in the day; she was relieved almost as by magic.

Although less prompt in its action, you saw the large nodes on the forehead of Williams in No. 2 Ward gradually vanish under its use. Wallace made some amends for the grievous offence he was guilty of in inoculating healthy subjects with the poison of syphilis.

(To be continued.)

[Abstract of a Paper read before the British Association for the Advancement of Science, at the meeting at Norwich, August, 1868.]

THE PHYSIOLOGY OF LANGUAGE.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.

Defects of language nearly always occur with a certain form of paralysis on one side, called hemiplegia, and the right is usually the side paralysed.

Hemiplegia is paralysis of those muscles which can move independently of those of the other side—*i.e.*, of certain muscles of the face, tongue, arm, and leg; not of the muscles which act bilaterally. Or, in technical terms—

It is a paralysis of the muscles engaged in chief voluntary operations. The bilateral muscles used in all (physically) involuntary, semi-involuntary, reflex, automatic, &c., processes escape.[1]

This kind of paralysis depends on damage to the *very highest parts of the motor tract*—viz., the corpus striatum, or thalamus opticus (in cases complicated with defects of language usually, probably always, the corpus striatum). In other words it shows loss of function of a motor centre, which is *embedded in the cerebral hemisphere*; or, to speak metaphorically, which *lies close upon mind.* In loose language, the corpus striatum is the "way out" from the chief organ of mind—through series of centres—to muscles which serve in intellectual and voluntary actions.

Damage to the hemisphere near the corpus striatum produces those defects which have been called aphasia, alalia, aphemia, aphrasia, asphrasia, aphthenxis, defects of intellectual language, cerebral loss of speech, &c.

TWO KINDS OF LANGUAGE.

Healthy language is of two inseparable yet distinct forms:

I. Intellectual—*i.e.*, the power to convey propositions.

II. Emotional—*i.e.*, the ability to exhibit states of feeling.

The two are separated by disease. It is intellectual language alone which suffers in most of the cases to be described. Emotional language usually escapes altogether.

Intellectual language suffers *throughout*—not only in its most striking manifestation in (*a*) words, but in (*b*) writing, and (*c*) sign-making.

It is the power of intellectual expression by "movements" of any kind which is impaired—those most special, as of speech, suffering most; those of simple sign-making least, or not at all.

Emotional language is conserved *throughout*, not only in its most striking manifestation, by (*a*) variations of voice, but in (*b*) smiles, &c.; and in its most simple manifestation by (*c*) gesticulation.

Although thus circumscribed by the term defects of intellectual language, there are within this limit many varieties of defects met with in actual experience.

It is easiest to say what they are *not.*

1. *They are not defects of voice.*—The patient who cannot *say* anything will vary the tone of his stock phrase or jargon and may be able to sing.

2. *They are not defects due to mere paralysis of the tongue and other articulatory muscles.*—Nevertheless the defect may be when most rudimentary a disorder of articulation (Ataxy); but this differs very widely from paralytic articulation.

The tongue is not paralysed even when the patient may not be able to put it out *voluntarily.*

3. *They are not owing to any fault in the outward organs of reception.*—The patients are not deaf mutes. Speech *has been lost* suddenly after being fully acquired.

THE SPECIAL NATURE OF THE DEFECTS OF INTELLECTUAL LANGUAGE.

The author arranges the cases he has to mention for convenience of exposition in two classes. In the first class the author supposes that the sensori-motor processes for speech are more or less *destroyed*; in the second that they are *unstable.*

Class I.—Severe cases in which the patient is speechless or nearly so, or in which speech is very much damaged. In the worst of these cases the patient can only utter some one unvarying word or two words, or some jargon.

He relates several cases varying in severity. In these cases power to read write and make simple signs is impaired, but the facts bearing on reading, writing, and sign-making in the cases related will be more conveniently considered after Class II.

Class II.—Cases in which there are plentiful movements but wrong movements, or *plenty of words but mistakes in words.*

Under Class II. he points out that taking the phenomena of many cases, we find evidences of damage to sensori-motor processes, higher or lower in evolution according to (*a*) Complexity of movements. (*b*) Width of interrelation. (*c*) Number of associations from ataxy of the grosser movements of articulation to an "ataxy" of movements embodying ideas. He is obliged, however, to speak of sounds, taking it for granted that in the following phenomena (1), (2), (3), &c., the disorder is of evolutions of movement and sensation in the triply-compound ascent just mentioned.

1. Ataxy of articulation—often an unintelligible gabble.
2. Alterations of words, as "sift for "stiff."
3. Alterations of syllables, as "gippin" for "pigeon."
4. Mistakes in words—recognisable symbols—(*a*) Related more or less in general idea, as "dinner" for "breakfast," "smell" for "taste." (*b*) Related in sound, as "Dustman" for "Busman." (*c*) No traceable relation, as "Where is the wind?" for "Where is the ink?"
5. Mistakes in compound symbols. (*a*) Related clearly in idea—"What am I to say it is o'clock?" for "What day of the month am I to put down?" or (*b*) obscurely related, as "*When the warm water* comes all the *weather* will go away!" for "When the sun comes out all the fog will go away."

When the defect is of processes so high in complexity, (interrelation and association) there is usually a traceable similarity, although it may be vague and deformed, betwixt the phrase used and the one intended.

6. Probably such defects as the following are of processes higher still, "Light the fire up there" for "Light the gas."

He then considers very generally, and with regard to all varieties of cases, the defects in complimentary modes of intercommunication which accompany defects of speech, and takes the opportunity of considering a question asked, "What is the degree of intelligence these patients have?" He expressly guards himself against any implication that language and thought exist separately. The question is not How is general mind damaged? but What aspect of mind is damaged?

---

[1] It is pointed out later in the paper that the fact that the unilateral muscles of one side only suffer when part of one of the corpora striata is destroyed, does not imply that the bilateral muscles (or the centre or centres for rudimentary bilateral) movements are not represented in the corpora striata.—This is an exposition of Broadbent's hypothesis. "An Attempt to remove the Difficulties attending the Application of Dr. Carpenter's Theory of the Function of the Sensori-motor Ganglia to the common form of Hemiplegia." By W. H. Broadbent, M.D. *Med. Chir. Review*, April, 1866.

He considers the mental condition of patients Classes I. and II. as regards—(*a*) Sign-making—simple. (*b*) Writing. (*c*) Ability to understand what is said to them. (*d*) Ability to repeat words said to them. (*e*) Reading. (*f*) Ability to play games. (*g*) Counting. (*h*) Music.

(*a*) *Sign-making* is least affected, sometimes seeming to escape altogether. He urges that we should distinguish in degree betwixt power to make simple signs which idiots can make, and the elaborate signs—saying nothing of finger language—which people make who are healthy, except for congenital deafness, and that we should observe if the patients can make signs to signify abstract quality as "blackness."

(*b*) *Writing.* This suffers more or less in nearly every case of defect of speech from disease of the hemisphere, but varies as much as the defect of speech itself does. Indeed, writing, and we may add reading, is the same defect in another form. For in each we have to reproduce the motor symbols of the words. Written or printed symbols are *symbols of symbols.*

The patient may (1) not write at all; may (2) scrawl; (3) make pothooks; (4) write bits of words; (5) may write plenty of words, but omit words and spell badly.

The patient who cannot write can usually *copy* writing correctly.

Patients can often sign their own names without copy when they cannot or will not write anything else.

(*c*) Do the patients know what is said to them?

It is usually held that "aphasic persons" do. The author thinks they usually do when they are speechless except for some unvarying jargon, *i.e.*, cases in Class I., but that when—cases in Class II.—they have free but disorderly utterance so high as mistakes in words they often do not understand, *i.e.*, quickly understand words said to them?

(*d*) Can the patients repeat words said to them?

They cannot in Class I.; in Class II. they can, with or without blunders.

The author supposes the reason in (*c*) and (*d*) to be:

That in Class I., the sensori-motor arrangements for speech are *destroyed* in their *lowest* processes by *limited* disease near to, and involving the corpus-striatum. The sensory aspect of the sensori-motor processes of mind is not reached. It is the "way out" which is broken up.

That in Class II., the sensori-motor processes are impaired but not destroyed, and that the change is not limited to the region of the corpus-striatum, but reaches deeper in brain.

(*e*) They cannot read, but they can—often at least—understand what is read to them.

(*f*) and (*g*) These points are very cursorily considered.

EDUCATED MOVEMENTS.

The movements of speech are educated movements and thus differ widely from those movements which may be said to be nearly perfect at birth, such as those for respiration, smiling, swallowing, &c. All the muscles represented in the corpus-striatum unilaterally[1] require a long education, and the most special of these are those engaged in the movements of speech, and next those of the arm. The muscles (see p. 3) always acting bilaterally, and chiefly represented bilaterally in the corpora-striata, are born with their centres for movements nearly perfect. Thus then the term "Intellectual language" merges in the larger term "Special movements acquired by the individual," and the term "Emotional" language in the term "Inherited movements," (common to the race). There is a still more fundamental distinction.

THE MOST GENERAL NATURE OF THE DEFECTS.

The author first considers Class I. Here the words previously used give way to terms larger still. In its highest or worst form it is a loss of *voluntary* power with conservation of involuntary capability.

(*a*) The author first illustrates by the case of gross movements, *e.g.*, a speechless patient may be unable to put his tongue out, although it moves well in reflex, &c., processes.

He next shows that there is a corresponding difference even in quasi-mental movements. "Speechless" patients sometimes ejaculate involuntarily.

Here again, taking into consideration the phenomena of many cases, it will be seen that there is, so to speak, an ascent in "compound degree" from utterances, like the common explosive oath, most *generally* related to *general* external circumstances, to actual propositions *specially* related to *special* external circumstances—*i.e.*, until the difference betwixt voluntary and involuntary utterance is effaced.

(*b*) It will be found that some of those patients who cannot talk voluntarily can swear. They utter other ejaculations which are of the same category—meaningless for the expression of ideas about things although useful as vehicles for the exhibition of feeling. They swear or ejaculate when excited and cannot repeat the words of the interjectional utterances when they try.

(*c*) Next he instances ejaculations more appropriate to the circumstances under which they are uttered, and which are a step higher in speciality.

(*d*) Next, and highest, a man usually utterly speechless may get out an actual proposition.

The above-mentioned series of phenomena show, the Author thinks, that there are sensori-motor processes for words somewhere, though usually the "will" cannot get at them.

This somewhere can scarcely be on the *left* side of the brain, for damage of this side has made the man speechless. These involuntary utterances are, the author supposes, the result of action of the *right* side. In other words, he thinks that the left is the leading side, and the right the automatic.

THE WILL.

He then tries to shew the relation of the so-called "will" to the rest of sensori-motor processes, and this time takes his illustrations from the stock-words or phrazes which the patients always use. First, he points out that it is probable that the stock phraze was the leading sensori-motor process, when the brain was suddenly damaged, and speaks of two cases in illustration. A man becomes speechless after hard work at *making a catalogue,* and can afterwards say only, "List complete." (Recorded by Dr. Russell, of Birmingham.) Another man receives a wound in the left hemisphere *in a brawl,* and can only say, "I want protection."

He then speaks of Spencer's views on the "will," and as he believes in accordance with those views, calls the "will" the *leading* sensori-motor process of the moment—there being no such separation as Will *and* Mind.

THE LEFT SIDE OF THE BRAIN THE LEADING SIDE, THE RIGHT THE AUTOMATIC.

The author does not think as Dr. Moxon does, that the left side of the brain only is educated, but that both are educated. It is certain that damage to the right side of the brain produces no defect of speech in most cases, and equally certain the author thinks that the disease of the left side only does not prevent the patient getting out words when a forcible circumstance outside himself is in very special relation with the processes for those words. For he points out that although there is in cases of involuntary ejaculation no prompting by the will of the patient so to speak, the occasional utterances are developed with more or less appropriateness to the then external circumstances.

---

[1] It is true that the tongue acts bilaterally, and that it is represented on both sides of the brain. But still it differs from other muscles acting bilaterally in that each of its sides has a distinct representation in its corresponding (opposite) side of the brain.—See Broadbent's paper, Med. Chir. Rev., April, 1866, p. 479.

Although the cerebral hemisphere are twins, the left may, if we accept Gratiolet's[1] statement, be said to be the first-born. It is born with the lead, and thus a patient who has damage to the left side of his brain cannot initiate movements on the undamaged right side, either objectively as in talking, or subjectively as in reading.

The author has recorded a case of loss of intellectual language in a patient who was *left-handed*, but states that in other cases this explanation will not apply, and he admits that there are cases of defect of intellectual expression with *left* hemiplegia which cannot be explained. Some of the patients, however, have been previously paralysed of the right side—although perhaps without any accompanying defect of speech. Still he has never seen a case of disease of the right hemisphere only as proved post-mortem with defect of speech of any kind, but has recorded three cases in which this side of the brain (including Broca's convolution) was diseased without defect of speech. And all are agreed that when hemiplegia occurs with loss of speech, the hemiplegia is *nearly always* of the right side. He has, however, received reports of two cases—one recorded by Dr. Long Fox, of Bristol, and one by Dr. Pye Smith, in which the Broca's region (on the left) was diseased without loss of speech.

LOCALIZATION.

The author does not attempt to localize language in any limited spot. The object is to find in mind the latitude and longitude of the defect, and in brain the corresponding latitude and longitude of the *damage*—the corpus striatum being the Greenwich.

Destruction of parts of the hemisphere at a distance from the motor tract *need* produce no *obvious* mental symptoms of any kind. An equivalent quantity of destruction of parts near the (left) corpus striatum will, however, cause defects of intellectual expression. He thinks that the quantity of defect depends generally on the (1) quantity of destruction of tissue, and (2) on its nearness to the highest part of the motor tract (the corpus striatum), "the point of emission of the orders of the 'will' to the muscles." (The author here quotes Mr. Dunn, who has long held essentially similar opinions).

He next proceeds to show that there is a more special kind of localization. He believes the principle of localization is essentially the same as that given by Spencer.

Taking the corpus striatum and optic thalamus as the illustration, the author speaks of the "localization of the limbs." He thinks the facts supplied by an observation of many cases of damage to these bodies show—

1. That both the arm and leg are represented throughout these bodies.

2. That there is an order of representation according to the "intelligence" of parts.

The arm is *more* represented than the leg, the hand than the arm, and the thumb and first finger than the rest of the hand.

3. That there is also a representation of speciality, there being localities where even the less intelligent parts have the leading representation.

Or, putting the above in another way. He thinks that pathology shows the corpus striatum to be made up of physiological units—this term he takes from Spencer—each representing potentially the whole of the limb. Yet that these are not repetitions of exactly similar units, but that each unit superintends a *different* movement of the *whole* limb.

So admitting that speech resides in each part of the brain, he supposes that there are points—probably in Broca's convolution—where the most immediate processes for talking are *specially* represented, and that there will be others near the corpus striatum where other acquired "faculties"—for instance, the movements of the arm for playing the violin, &c., &c., are *specially* represented, but that there is no localization in the sense that one part superintends one thing and no other.

The corpus striatum represents, to use arbitrary terms, the highest *physical* evolution of movements for articulation, for the arm and for the leg; from this point start the *psychical* movements of speech.

It is thus interesting to inquire if there be not starting from the corpus striatum a traceable evolution of movements for the educated psychical movements of the limbs. The author believes the phenomena of certain nervous diseases show disorder of the most rudimentary of these processes.

◆

Legal Intelligence.

CONVICTION OF A SURGEON UNDER THE VACCINATION ACT.

At the Southwark Police-court, on Thursday, Mr. David Roberts, M.D., of Great Dover-street, Borough, was summoned by the parish authorities of Camberwell for that, on or about the 4th of June, being a medical practitioner, he did refuse to fill up and sign a certificate of the successful vaccination of Henry Lownds, when submitted to him according to law, he having successfully performed the operation upon such child.

Mr. Irving, the clerk to the board of guardians, attended to prosecute, and stated that the present proceedings were taken under the provisions of the 23rd and 30th sections of the Vaccination Act, passed in 1867, which set forth that whenever vaccination was performed successfully by a medical practitioner he must fill up a certificate to that effect, and forward it to the registrar of the district, or render himself liable to a penalty of 20s.

Mr. Partridge asked if the act said anything as to fees to be paid to them.

Mr. Irving replied that there was nothing said about fees excepting to the duly appointed medical officer. It was quite clear that every medical practitioner who successfully performed vaccination was bound to fill up the certificate.

Mr. Charles John Nicollas said he was registrar of births and marriages for the sub-district of Peckham, at the parish of St. Giles, Peckham. It was part of his duty to give notice to parents on the registration of the birth of their children to have them vaccinated. On the 21st of February he registered the birth of Henry Lownds, born on the 11th of January, when he gave the father a vaccination certificate (produced) to be filled up by the medical practitioner. He afterwards received information that the defendant had successfully performed the operation, but refused to fill up the certificate. Witness wrote to him about it on the 4th of June, pointing out the section of the Act of Parliament bearing on the case, when he sent a reply refusing to fill up the certificate, as he was not paid for it. In consequence of that the Board of Guardians directed the present proceedings to be taken.

Elizabeth Lownds said that the child was born on the 11th of January, and on the 21st of February it was registered through her husband by Mr. Nicollas. She received a certificate, to be filled up by Dr. Roberts, which he refused to do, saying it was of no consequence.

Mr. Partridge here said that on looking at the act the 22nd section mentioned that no fee should be taken by the public vaccinator, or any medical practitioner, on giving his certificate, which seemed to be imperative.

---

[1] Gratiolet's observations show not only that the *frontal* convolutions (the convolutions specially related to the corpus striatum, which is a centre *chiefly* motor) of the left side are developed in advance of those on the right, but that the sphenoidal and *occipital* convolutions (the convolutions specially related to the thalamus opticus which is a centre *chiefly* sensory) are in advance of those of the left. May we not suppose that the right is the leading side, and the left the automatic side for "educated sensations!" Such "crossed action" of the brain would be in accordance with the crossed action in the spinal cord which Brown-Séquard's researches have established, and is in accordance also with the law of the orderly distribution of motor and sensory nerves laid down by Hilton and Schroeder van der Kolk.

Mr. Irving said that the public vaccinator was appointed by the Board of Guardians and paid by them. If a private medical practitioner performed the operation he should seek his fee from the party employing him, but he was bound to sign the certificate or abide by the penalties specified by the Act of Parliament.

Dr. Roberts considered that there was nothing in the Act of Parliament compelling him to sign the certificate. If so, it was very hard upon the Medical Profession altogether. It never could have been the intention of the Legislature to impose upon medical gentlemen the duties of signing such certificates without any remuneration. He successfully vaccinated 600 children in the course of the year, and it would be hard if his time was to be taken up without any fee or reward.

Mr. Partridge said it was a question of law, and the defendant did not dispute the facts. He had refused to fill up the certificate because he was not paid any remuneration. The 23d section of the act was clear upon that point :—" Whenever any successful vaccination is performed by a medical practitioner he is bound to sign and forward a certificate to the registrar of the district." There was nothing to show that he had not the remedy of getting his fee as a private practitioner from the party who employed him, but it was clear that he was bound to give his certificate to the registrar without fee. The fine under the 30th section of the act was 20s.; but as the defendant had only come forward to meet the case on those peculiar grounds he should mitigate it to 10s. and costs.

Dr. Roberts asked his worship to grant him a case for the Court of Queen's Bench, as it was most important to the medical profession.

Mr. Partridge declined to do so, and told Dr. Roberts that if he thought proper he could apply to the Court of Queen's Bench.—*Standard.*

THE NEW EXAMINATION FOR PHARMACEUTICAL ASSISTANTS.

The following proposed regulations for the modified examination for assistants under the Pharmacy Act, 1868, have been submitted to the Privy Council :—

"Candidates will be examined in the following subjects :—

"Prescriptions.—Candidates will be required to read autograph prescriptions, translate them into English, render a correct translation of the directions for use, and detect unusual doses.

"Practical Dispensing.—To weigh, measure, and compound medicines, write the directions in suitable language, finish and properly direct each package.

"Materia Medica and Quality of Specimens.—To recognise the Pharmacopœia chemicals in frequent demand, and specimens of roots, barks, leaves, fruits, resins, and gums in ordinary use ; the following plants, either in a fresh or dried state, or from plates—Belladonna, stramonium, hyoscyamus, conium, aconitum, digitalis, and sabina; also to estimate the quality of each specimen submitted and its freedom from adulteration.

"Pharmacy.—To recognise the preparations of the Pharmacopœia which are not of a definite chemical nature, such as extracts, tinctures, and powders, and give the proportions of the more active ingredients.

Correspondence.

THE TITLE OF DOCTOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the important letter of Dr. Davey in your last issue there is incidentally raised a question, on which I am astounded to see so excellent a reformer as the President of the Medico-Political Association defend men who have not a degree assuming the title of doctor.

Instead of the bye-law forbidding the registrar to address as "Doctor" members who were not graduates being "infamous," it is to my mind one proof that some honesty still remains in the old club in Pall-Mall. If such an epithet is at all applicable, I should say it were more appropriate to the conduct of those who hold themselves out as Doctors of Medicine, when they have no right to do so. The degree of Doctor of Medicine is only conferred by Universities. A man has no more right to assume it because he possesses a licence to practise physic, than a solicitor to assume the degree of LL.D. If a member of the College of Physicians is a doctor, so is a licentiate—the title now appropriate to the general practitioner. If a licentiate of the college may take the title, why not a licentiate of the Apothecaries' Company, whose legal right to practise is much clearer. The examinations are not very different, and the Hall, in spite of all the odium cast upon it as a trading depot, has never yet sold its diploma. Trading company, indeed, pshaw ! Why this immaculate college, sir, which so despises trade, openly sold its diplomas of membership at ten guineas each. The trading company has had sufficient trade-honesty to give value in return for cash, and to refrain from the infamous traffic (in diplomas), which has been so profitable to colleges of physicians—which are *above trade!* (Save the mark !) Well, sir, if a purchased diploma is to give the title doctor, why not at once give up all university distinctions ? or at least let a license to practise obtained by such an examination as the Apothecaries' Company give an equal title.—
I am, &c., M.D., L.S.A.

THE LONDON COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The letter of Dr. Davey on the "Fellowship of the Royal College of Physicians of London" touches on several points in reference to this oligarchical corporation which ought to interest all true medical reformers. The one point, however, of extreme importance is the proposal to recognise the existence of that non-descript class of persons yclept members. This is indeed not the first time such a just measure has been proposed, and I hope the agitation existing may not end until justice is done.

Dr. Davey is probably aware of the details of a large scheme of medical reform sketched by Dr. Prosser James, in his address to the members of the Scottish Universities already published in your paper, and he may have seen the correspondence that has been elicited on the question. Now, what I wish to point out is that the proposal of Dr. Prosser James includes such a reform of the College of Physicians as that advocated by Dr. Davey, and therefore deserves his active support.

Surely Dr. Davey's sympathies are not confined to his own college. He can see and feel the injustice perpetrated by every one of the corporations, which has been so often denounced in your columns, and the reform of all of which is as necessary as that of Dr. Davey's college. Every corporation needs reform, and because the plan of Dr. Prosser James accomplishes this, and through this the reform of the Medical Council, it is unquestionably the most important scheme ever submitted to the profession. I ask, therefore, Dr. Davey to step out of the ranks of his own college, look upon medical reform in a larger sense, and support the only plan that is both effectual and feasible.

Dr. Davey and other members of the Pall-Mall College are anxious to reform that corporation. Dr. Prosser James risks his election by giving so much prominence to a reform of *all* the medical corporations. Surely he may hope for the support of the advocates of the partial reforms which his complete scheme involves. Let Dr. Davey say what he will do in the matter.—I am, &c.,

A Member of Three Corporations.

LORD AMBERLEY ON LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Although I agree with much that you have written respecting the opinions advanced by Lord Amberley at the late meeting of the Dialectical Society, I confess that, to my mind, you have scarcely done him justice. Admitting the interpretation you have put upon his lordship's words as a possible one, I think it may fairly be said that this is pushing things to an extreme, and although that may serve the purpose of his political opponents it could scarcely actuate a medical journalist.

As your report shows, Lord Amberley distinctly condemned abortion, and if he did not venture on as long a moral essay as you have done, it is but just to remember that that crime was only vaguely connected with the subject proper of the debate, and that each speaker was limited to 15 or 20 minutes. How impossible it is in such a short time to give a complete sketch of a large question, I need not remind you.

Whether the Malthusians are right or wrong as to its cause, no one can deny the existence of much distress, and it is, to say the least, rather uncharitable to put the worst construction on the words of those who seem to have committed themselves to the doctrine of a philosopher who has had enough obloquy cast on his name. It would appear, from many facts that have lately transpired, that the theory of Malthus is likely to be again hotly contested. Whether true or false, discussion if carried on in a spirit of truth-seeking must be beneficial. But any attempt to excite prejudices against it by making it appear to justify immorality, should be repudiated by every one who, like your correspondent, is

Not a Disciple of Malthus.

Mid. 1867, K.Q.C.P.I. ; John Nyham, Drimoleague, county Cork, Lic. R. Coll. Phys. Edin., 1868, Lic. R. Coll. Surg. Edin., 1868 ; T. Browne Macauliffe, Newcastle, W., Limerick, M.D., 1868, and M.Ch., 1868, Qu. Univ. Irel. ; James Love, Lislaird, Castlederg, county Tyrone, Lic. R. Coll. Phys. Edin., 1868, Lic. R. Coll. Surg. Edin., 1868 ; Francis Edward Clarke, St. Helen's, Dunfanaghy, county Donegal, M.B. University of Dublin, 1868.

Speaking of the elevation of M. Nelaton to the office of Senator, *L'Union Médicale* states that during the first Empire but one physician was raised to a like position, M. Cabaius. No one is authorised to say, observes the same journal, that any condition has been imposed upon M. Nèlaton. He has not announced any intention to retire from practice ; however, of his own accord, he last year resigned his professorship.

Medico-Chirurgical Society of Clasgow.—At the meeting of this society held on Friday, 4th September, in the Hall of the Faculty of Physicians and Surgeons, the following gentlemen were elected office-bearers, viz.:—President —Dr. J. G. Fleming. Vice-Presidents—Dr. W. T. Gairdner, Dr. E. Watson. Council—Dr. Dewar, Mr. Tindal, Dr. G. H. B. Macleod, Dr. A. R. Simpson, Dr. Richmond, Paisley; Dr. F. Thomson, Mr. Torrance, Airdrie; Dr. H. Thomson. Secretaries—Dr. James Adams, Dr. R. Perry. Treasurer—Dr. H. R. Howatt.

Royal Sea-Bathing Infirmary, Margate.—The annual meeting of the governors of the above institution was held lately at the hospital. The total number of patients under treatment had, during the year, been 894, the greater part being from London and its neighbourhood. More than half were discharged cured, and the great majority of the remainder left materially benefited. There are 250 beds now in the hospital, all of which are fully occupied during the greater part of the year, and more than half the number during the winter months. The institution is now kept open for the whole year instead of the summer months only, this desirable alteration having been accomplished through the success attending the "fund in aid" derived from the 5s. annual subscriptions inaugurated thirteen years since by the Rev. Mr. Hodgson, the honorary secretary ; the number of subscribers to this fund last year amounting to about 7000. The amount produced last year had been £1653. During the last year an addition had been made to the north wing, by which accommodation had been obtained for twelve more beds, and another addition was contemplated on the west side, which would provide accommodation for eighteen more beds. The total income for the year, including £2000 received from patients, £1653 from 5s. subscriptions, £1254 donations, and £450 legacies, had been £13,962, 19s. 11d., and after investing £5500 and paying all expenses of the hospital, there was a balance in favour of £1208, 9s. 3d. The chairman, in moving the adoption of the report, said it was essentially a London hospital, nearly all its patients coming from the metropolis. The report was adopted, and a vote of thanks passed to the Rev. Mr. Hodgson for his valuable services. According to annual custom the hospital was then thrown open for a public visitation, and a large number of visitors to Margate and Ramsgate availed themselves of the opportunity of inspecting it. At three o'clock in the afternoon, a public meeting was held in the dining-hall, for the purpose of explaining the objects and usefulness of the institution.—*The British Medical Journal.*

The Royal Hospital for Imbeciles, Putney.—A gratifying meeting took place in the general room of the above institution on Monday evening. All the patients, male and female (except those who were bed-ridden or too ill to attend) assembled together to celebrate the first anniversary of the appointment of the present governor and matron (Mr. and Mrs. Haughton). The governor, with his usual good-nature and kindness, had provided (out of his own pocket) special refreshments for the occasion, and he and his wife amused them for several hours with music, singing, recitations, and readings, which seemed to be thoroughly enjoyed. The superintending nurse, who is very popular with the patients, had at their wish collected small contributions from those who desired to give, and purchased two handsome dressing-cases for presentation to the governor and matron, as an acknowledgment of their unwearied efforts to promote the comfort and happiness of the inmates generally. These dressing-cases, with an appropriate address, were presented, and the governor, who was unprepared for such a demonstration towards him, was quite overcome at the cordial and enthusiastic manner in which the presentation was made. It is hoped that the vastly improved condition of this institution under the efficient management of Mr. and Mrs. Haughton will be properly appreciated by the authorities of this useful home for the afflicted. —*Medical News.*

The fair sex of Marseilles have taken to poisoning their liege lords. Three women have been arrested there on the charge of disposing of their husbands in order to get married to other Lotharios with whom they were on terms of intimacy. On Saturday the magistrates, accompanied by the Procureur Imperial and medical men from the hospitals, went to the cemetery and exhumed the bodies in presence of the accused. One of the latter, 35 years of age, when she saw the corpse of her late partner, who died in January last, showed signs of great emotion ; the second, about 45, a widow since May, exhibited great coolness ; whilst the third, a young person of 20, whose husband only died a month back, was, according to the local papers, "greatly" moved. The intestines and viscera of the deceased were handed over for analytical examination. The prisoners are said to have obtained the means of committing their crimes from an herbalist, who is also in prison.—*The Standard.*

The dentists of the Province of Ontario have recently formed themselves into an association, and obtained an act of incorporation from the local legislature. This association holds regular meetings, and discusses subjects of practical interest to the profession. With a view of supplementing this important movement the projectors of the *Canada Journal of Dental Science* are desirous of supplying a means of intercommunion which no foreign journal can be expected to supply. We trust this worthy undertaking will be well sustained, and that the *Canada Journal of Dental Science* will take rank amongst the leading periodical literature of the Dominion. The journal is to be under the editorial management of J. Stuart Scott, M.D., Cobourg, P. O., and of W. George Beers, Esq., Montreal.—*Canada Medical Journal.*

Torture in Russia.—M. Emile Andreoli, who took part in the last Polish insurrection, and on being captured by the Russians was sentenced to twelve years' imprisonment in Siberia, has just published in the *Revue Moderne* the first part of his prison recollections, some of which are certainly curious. "I was told," he remarks, "that on two or three occasions an electric battery has been made use of by the Russian police to loosen the tongues of the prisoners who refused to answer the questions put to them, which shows that the Russian Government is one of progress and knows how to turn the discoveries of science to account. After all, this was not more cruel than the torture of the herring. I knew several who underwent the latter, and they told me that nothing could compare with the sufferings which they endured. They were confined in a well-warmed apartment, salted herrings with bread and water for the first few days being their only food. If they refused to answer the questions of the examining commissioners the bread was first of all withdrawn, and then the water, whereupon the torture of intense thirst commenced, depriving the sufferer of all moral strength, and even making him abandon the resolution which he had formed to die. Very rarely did anyone remain mute when brought before the commissioners a second time. The sittings were usually at night, in a splendidly-lighted apartment, with refreshments of all kinds temptingly displayed on the side tables. The president would usually be most gracious. 'By-and-bye (he would say) we will, if you like, ask you to have something to drink with us.' The fever and the vertigo caused the prisoners to lose their reason, and they generally yielded. Hunger would not have brought about the same result as thirst, which loosens the tongue even far more readily than drunkenness does."

Death of Dr. Rogan.—The sudden death of one of our most esteemed and best beloved citizens has brought sorrow to the hearts of all, and has plunged his many friends into profound grief. At the County Lunatic Asylum, on Sunday morning, died Dr. Rogan, the Resident Physician of that Institution. Son of one of our most respected local medical men, and nephew of another, whose professional eminence was national—he was trained for the same calling. To a rare amount of natural talent, was added an education, as perfect as industry and perseverance in the best schools and under the best masters, could make it. At college he distinguished himself as a first-class prize-man in more than one branch of natural science, and his love of learning was such as to make him an earnest student to the end of his life. His knowledge and attainments, as a physician, were held in high estimation by his brethren, who often asked for his assistance in cases requiring more than ordinary acumen. We have further heard it said by competent critics, that his judgment and skill as a surgeon were such as would have placed him in the front ranks of metropolitan practice. His tastes, however, were different, and his ambition soared no higher than the office he held. He gave up a growing practice, and confident hopes of eminent and lucrative position, to hold the unobtrusive appointment of Resident Physician of the County Derry Asylum. Here his energies were chiefly devoted to the study of mental disease, and to the treatment of his unfortunate patients, duties for which he was, in all respects, eminently qualified. But it was not merely his talents, or his attainments that won the love of all who knew him. The remarkable geniality of his disposition, his imperturbable sweet temper, his kind and unselfish life, have endeared him to persons of every class and denomination, and rendered his death a public loss. His unexpected removal was caused by disease of the heart. We learn that his professional brethren have asked permission to attend the funeral as mourners; and that a similar tribute of respect is intended by the members of the Society of Freemasons, of which he was a distinguished brother and a bright ornament. —*Londonderry Standard.*

Death of an Eminent Physician.—The death is announced of Dr. Clot.-Bey, one of the notabilities of Marseilles, at the age of 75. He had acquired a well-merited reputation by his success in establishing medical instruction and practice in Egypt. During the last ten years he lived in France in retirement, but had long been associate of the most important academies of Europe, and Commander of the Legion of Honour.

NOTICES TO CORRESPONDENTS.

Proofs reaching authors in England on or before Friday morning are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper only.

All Communications and Letters must be authenticated by the name of the writer, though not necessarily for publication.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (King's Coll.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

DEATH VACANCY.—In one of the best suburbs of London, the decease of a gentleman, in high class practice, affords an unusually favourable opportunity for the introduction of a successor. The receipts during the last and the present year are at the rate of £1300 a-year. Usual midwifery fees from £2, 2s. to £5, 5s. The connection lies within a radius of a mile, and is easily conducted. The practice is in the care of a thoroughly competent gentleman, associated in the practice with the deceased, and well-known amongst the patients, he will remain as *locum tenens*, and will, if desired, cooperate with the widow in the introduction. The house is convenient and well situate, with garden and stabling; rent £110 a-year. The successor must be doubly qualified, and accustomed to good society. Address X. 367, care of Mr. Langley, as above.

A very Profitable Medical Establishment in London is for sale, the proprietor retiring. Average income £400 a-year, derived from private practice and an open surgery. The house is held upon beneficial lease, with garden, stable, and yard. Terms moderate.

LONDON.—In a good suburb, a Partnership for Transfer. Present income upwards of £2000 a-year, and capable of still greater increase. The house is well situate; rent £100 a-year. Address X. 361, Mr. Langley, as above.

MIDLAND—PARTNERSHIP.—There is an opening for a Junior Partner in an old-established Practice in a good town. The successor must be a Gentleman of superior education. Income £1400 a-year—capable of great increase. A Third Share to be negotiated upon the basis of two years' purchase. There is no dispensing, and the fees are good. Excellent residence; rent £50. Address X. 365, care of Mr. Langley, as above.

IN a pleasant country town, a Practice for Transfer. Receipts £450, appointments £260. House very convenient, with garden and stabling. A year's introduction given if required. Address X. 360, Mr. Langley, as above.

SOUTHERN COUNTIES.—For Transfer an old established Practice, in an improving district, within easy access of London. Receipts £1000 a-year; appointments £80. Population 2000, and only one opponent within three miles. House, with garden, stabling, &c., at a very moderate rent. As the vendor has the offer of a desirable appointment, a moderate premium would be accepted. Address X. 359, Mr. Langley, as above.

IN the suburb of a pleasant and enlarging town, within easy access of the sea, a good class Practice for Transfer. Twelve months' partnership introduction if desired. Income averages nearly £600 a-year; but the practice has been restricted by the ill health of the vendor, who is thus compelled to retire. The house is one of the best in the locality; but its occupation is optional to the successor. Address X. 275, care of Mr. Langley, as above.

Now ready. Second Edition, with considerable additions.

IN compiling our Students' Number we have aimed not only at supplying Students with the practical information which they really want, instead of prolix and verbose official regulations, but at giving our subscribers and the profession some matter which may not be uninteresting, and which may, as far as possible, atone to them for the yearly trespass which, in the interest of Students, we are obliged to make on their forbearance. We omit nothing important. We simplify by removing from the official regulations the semi-legal fog in which their phraseology is obscured. Our Students' Number is for Great Britain and Ireland, not for London alone.

THE SELECTION OF A PROFESSION.

The boy at school, full of life and enjoyment of physical existence, has little inclination and few reasons to think of his future. It is not until nearly the end of his scholastic curriculum that either parents or youths ask themselves and each other the question what is to be done, and what the suitable prospective employment for the student? The boy chooses with too little care, the parent bestows too much anxiety upon the matter, as a rule; too little regard is paid to the special ability of the aspirant, and his father exercises too much influence to induce his son to follow a particular walk in life. We believe that every individual has a special fitness for something, and that fitness is usually indicated more by his habits than his words. The student may have heard a brilliant barrister plead in a case in which he was interested, and straightway is fascinated by a passion for the law, and declares that he will be a special pleader, with ambition to be keeper of the Privy Seal and Lord High Chancellor of England. But the young dreamer has no conception of the difficulties which must be overcome before he can hope to achieve even mediocrity in such a career, and unless he have special aptitude in a good memory, with capacity for using promptly the knowledge he has stored, and a fluency of speech to express it, he had better abandon the idea. Another student may have been impressed by the grandeur of an ecclesiastical ceremonial, and have been carried away by the didactic eloquence of a popular preacher—but before he decides to become a teacher of religion he must be prepared to forego all matters of worldly interest, and wholly to abnegate self in the considerations of the future. In this case, far more than in the former, the parent or guardian is bound to exercise his influence to induce the student to pause and to consider well what he is about to do. In fact, we are inclined to the opinion that so much discouragement should be shown in both cases as would deter the student selecting either law or religion as a profession, unless he were so resolved and felt so peculiarly fitted for it that his selection could not be afterwards set aside by opposition or difficulties. For the profession of arms much more than personal fitness and liking is necessary, because promotion, and indeed social position, can alone be secured by money and family influence. No young man of education, with a sense of self-respect, would ever enlist as a private soldier. We have thus glanced at three of the professions, leaving to the last that of medicine, because we propose to treat of its prospects, &c., more fully.

Before the schoolboy selects medicine as his profession, we advise him to consider the cost in brain and labour—not as deterrent, but because such consideration may prevent failure and disappointment afterwards. In the writer's experience upon a large scale he has come to the painful conviction that of those who enter the medical profession, at least one-third have wholly mistaken their vocation, and their mistake is not only a disaster to themselves and to their families and friends, but to a large number of poor creatures whose lives may be dependent upon them. The supposed free and easy life of a medical student attracts to our profession a number of young men who arely do any good for themselves, and are the source of infinite mischief to their associates—for no man can succeed in the medical profession without earnest self-denying work. The student, therefore, who enters at one of the hospitals with the idea of having an easy life before him makes a tremendous error ; he is sowing the seeds of certain misery for himself.

But what are the preliminary conditions of fitness in the student who proposes to enter upon a medical career? Good physical health is, in our opinion, essential to success. All the senses must be perfect, for all are called into requisition in our art—eye, ear, smell, and touch. But it is not merely to see a foul tongue or a dislocated limb ; it is not merely to hear a patient describe his symptoms or to listen to abnormal sounds in the lungs ; it is not merely to detect by the nose the foul smells which are associated with the physical surroundings of fever ; it is not merely to feel the pulse beating beneath the finger or to touch the end of a broken bone ; the mere exercise of the sense is of no value unless the senses are cultured in a high degree, and associated with good observant faculties. His senses must be subordinated also, for some of the duties which the physician and surgeons have to perform are at first repugnant and even revolting to the ordinary observer. Mr. Langley, in his "Via Medica," writing on this point says :—

"The youth who shrinks from these duties neglects golden opportunities which may, perhaps, make the difference between success and failure in after life. The senses of the surgeon have to be subordinated as well as cultured, and he must be prepared to see without shrinking that which appals and sickens the ordinary observer. His sense of duty must make him calm and firm, yet aware of all the agony his patient suffers. The noblest operator is the surgeon who is farthest removed from the butcher. Let the student therefore shun everything which is calculated to brutalise, whilst he seeks every occasion which can teach him benevolent firmness and imperturbable self-reliance. To make himself more and more fit to assist in emergencies is not merely to make the junior more valuable to the employer, but enhances his own self-respect and increases his power over his future destiny."

To the mind which finds its delight in the demonstrations of science and the applications of abstract truths to practical purposes, the study of medicine affords the grandest of all fields; but there are humbler and scarcely less useful paths of benevolence and usefulness which constitute the unwritten heroism of the every-day life of the ordinary medical practitioner.

The money value of the Medical Profession is not great, because, like all the learned professions, it is over-full, and therefore as a medium by which a fortune is to be made, it is not to be thought of. But even in this respect there is a better time coming, and the future of the general practitioner will be better than the past. Quoting again from Mr. Baxter Langley's "Via Medica," we would commend to the student who contemplates entering the Medical Profession the following remarks:—

"It appears to me a grave error to take a young man from school and plunge him at once into the theoretical studies of medical science, for it is absurd to expect that during the short space of four years he shall learn the laws of physics, chemistry, botany, zoology, human and comparative anatomy, pathology, practice of medicine, surgery, midwifery, and medical jurisprudence. My experience and observation leads me to the conviction that the most successful men are those who have some practical and general knowledge, and are able to observe and to manipulate well before they enter upon their attendance at lectures. Hence I am strongly convinced that a year or two well spent with a provincial surgeon is not time thrown away by the tyro in medicine. Students are apt to think that the whole object of their studies is to pass certain examinations; but thousands of men find out the burden and calamity of this mistake when they are called upon to prove their practical acquaintance with their profession under some sudden and terrible emergency. To know the theory of obstetric medicine—even to have attended a large number of ordinary cases of midwifery with success—is a totally different thing from being so thoroughly master of the subject that no emergency can arise for which the medical attendant is not prepared. Many a surgeon has turned pale at the bedside of his patient on finding himself suddenly in the presence of some difficulty which he does not clearly understand, and with which he is utterly incompetent to deal decisively. In such moments he would feel with deep acuteness that "cramming" and "grinding" will not alone make a professional man the "master of the situation," *semper paratus*, and ready for "the occasion sudden" with which the practitioner will from time to time be called upon to deal, and oftentimes alone. The student who resolves not only to appear, but to be, qualified to take any and every surgical or medical responsibility which can present itself will not be in a hurry either to begin or to end his curriculum; his whole purpose will be to gain knowledge and experience for its own sake, and to fit him to practise successfully. Other men may at the first seem to outstrip him in their apparent progress, but the man who is thoroughly grounded in his profession, and has become familiar with the principles of the sciences before he enters upon his lectures, will soon outstrip and take precedence of those whose attention to the higher branches of their profession is prevented by the necessity of studying outlines and elements which ought to have been learned before."

RECOMMENDATIONS OF THE GENERAL MEDICAL COUNCIL.

The General Council of Medical Education and Registration have issued to the various Licensing bodies, their suggestions on the subjects under their supervision. These Recommendations are not compulsory, and in so far as they have been adopted by the Licensing bodies provisions in accordance with them will be found amongst the regulations of each corporation in other parts of our issue.

The gist of these suggestions is briefly as follows:—

1. The student must pass his Preliminary Examination in General Education *before* he can be registered as a student, and not more than a fortnight after he commences professional study.
2. That twenty-one shall be the earliest age for qualification to practice.
3. That the examination be divided into two parts, one to be undergone at the end of the second, and the other at the end of the fourth year.

Public Services.

POOR-LAW.

In the first place, then, a young qualified practitioner, indisposed to be an assistant, and desirous of commencing general practice without investing any money in purchasing a succession, may, perhaps, obtain a poor-law appointment, though he should scarcely expect to obtain a livelihood from this inadequately remunerated employment.

ENGLISH POOR-LAW MEDICAL SERVICE.

Prior to the Metropolitan Poor Act of last year, the English Poor-law Medical Service may be said to have been in the hands of the guardians, supervised by the Poor-law Board. Each parish in England and Wales had its guardians of the poor, and these parishes were grouped together to form unions. The unions were divided into districts for medical relief. Union Medical Officers, therefore, have the care of a district, or sometimes the care of the workhouse of the union—sometimes of both. The officer was elected by the guardians, and the appointment approved by the Board. He was required to have both a medical and a surgical qualification. In some instances these were specified, but almost always the London College of Surgeons and Apothecaries' Hall were the two most favoured diplomas. For this reason London students will still continue to take these qualifications whatever else they may add to them. These appointments are not lucrative. In most cases the salary is very low. They are, however, sought after by young men as a means of getting into practice, and are often almost obligatory in the country to prevent fresh opposition being introduced. The Metropolitan Poor-law Act, 1867, assimilates the Poor-law, so far as London is concerned, to that of Ireland, and it will probably shortly be extended to the country. It establishes in London asylums and dispensaries, and distributes the cost of supporting them over the metropolis. The appointment of the Medical Officer will be made by the Dispensary Committee, but the Poor-law Board has power to modify many of the arrangements. The Poor-law Board is now a permanent body with increased powers, but since the Act so few improvements have been effected that the Medical Officers are very dissatisfied.

IRISH POOR-LAW MEDICAL SERVICE.
